The committee of management decided to invite some leading statesman to open the pier, and at the same time they issued invitations to a hundred or more of the leading people of the district. The statesman who consented to come was the Duke of Argyle, and never was choice happier. Punctually at noon his Grace, attended by the Marquis of Lorne, reached the small enclosed space near the entrance to the pier, where a chair had been put for him. He was received with deafening cheers. He first looked curiously round on the thousands before him, and far as the eye could reach they could be seen covering the heights and filling the ravines, and forming a *tout ensemble* rare in our dingy climate. After listening to the customary addresses (one of the best of these was read by Mr. McEwan Brown, the honorary secretary of the reception committee), his Grace gave one of those genial, scholarly replies for which he is famous. Looking behind him he pointed out the beauty of the water and the purity of the sky, and congratulated the residents on the exquisite climate they enjoyed—the best, he thought, in the world, for it was equally a stranger to the intolerable and scorching suns of Italy and Andalusia, and to the biting blasts of Canada and Russia. "You have not," he remarked, "the fierce sun of lower latitudes, nor the azure seas of Sicily; but where will you find a place in which a greater number of days can be agreeably passed in the open air?" "Among the addresses," continued the Duke, "for which I am particularly grateful, is the one which has just been presented by those Scotchmen who are residents at Bournemouth, and I am very glad to have a representative in Mr. McEwan Brown of that branch of the community, because I believe Mr. McEwan Brown has taken a prominent part in this undertaking that we are inaugurating to-day. I am glad to thank him as a representative of Scotchmen, because I gather from his double name—McEwan Brown—that he is partly a Celt and partly a Saxon, and that is my own position exactly. I am a Campbell on one side of the house, I am a Glasielt on the other, and the one is a highland and the other is a lowland name; and I have a theory that what are called pure races are less active and energetic than a mixed race. I believe that a great advantage that we have in England, Scotland, and Ireland, is that there is hardly a single man or woman who can say he is a pure Celt, Saxon, or Norman. We are all a mixed population; and in the case of our excellent friend, the lower animal, who is an especial friend to man—the dog—it is said that mongrels are bad dogs. But I believe mongrels are the best of men. After all, there is nothing strange in even pure Celts being in Bournemouth, although it is a long time since there were any in this country in their purity. But you have a curious recollection of it in some of the names in this country. I suppose some of you know that the river Avon, which flows out close to us into the sea at Christchurch, is a pure Celtic name. All over England, in many parts, there are rivers Avon, commemorating the period when the whole of this country, before the Roman invasion, before the Saxon invasion, before the Norman invasion, was inhabited by purely Britannic Celts. Therefore it is no strange thing if there were such a person as a pure Celt, if he could be found, inaugurating this work near the river Avon. Close to my door in Scotland there is another river called the Garavon, and that is precisely the same as the French Garonne. So interesting is it to trace the history of nations and the local names of a country such as this." He then declared the pier open, and, walking to the end of it, was followed by the notabilities of the district, among whom one of our contributors, the Rev. R. A. Chudleigh, Rector of West Parley, was not the least distinguished.

The new pier is 600 feet long and 38 feet wide. It is a noble structure, extremely handsome and light, going right out to sea, and standing at a considerable distance above the water. It is expected that it will shortly have a

regular service of boats, and there can be no doubt that it is a great boon to the neighbourhood, and will raise the value of property immensely; indeed, it will make Boscombe complete and practically independent of Bournemouth.

In the course of the day we learnt that the contractors, Messrs. McEwan Brown and Co., of Boscombe, had had to contend with many difficulties, but that they had overcome them all, and it was generally agreed that they had acquitted themselves perfectly.

At one o'clock the guests had luncheon in a large tent near the Chine Hotel, and then again, amid general applause, the duke gave one of his happiest speeches. He told his hearers that he had known Bournemouth longer probably than any of them, for it was forty-three years since he first came down as an invalid to see the place and recruit his health. Then Bournemouth was hardly known; indeed, he had not even heard its name until he was advised to visit it. He found the Royal Bath Hotel, which had only recently been completed, and about 2000 people, that was all. Vast pine woods extended in all directions, intersected by swamps, gulleys, and wandering streams. Since that distant day he had paid other visits, and now he found that the bantling of the last generation had become a giant; the rivers had been straightened and confined; roads had been cut in all directions, and whole towns had sprung up which, large though they were, seemed only to be the commencement of still greater things hereafter. The duke spoke of the natural wonders of Bournemouth, and these he thought were, first: its marvellous geological features; indeed, he said that there was no exaggeration in asserting that the spot on which he was standing and speaking was unlike any other in the United Kingdom, for where he was standing there had once flowed a mighty river, vast beyond conjecture, bringing down the sands of regions that must have enjoyed the climate of the tropics and carried a vegetation unlike that of any existing northern region. In those stupendous mounds of river sand which he saw all around were to be found the fossil remains of Araucarians, now confined to Australia, of Cacti, found only in America, and of palms only now growing naturally and luxuriantly in hot climates. "Where," he asked, "was the land from which that ancient river came? What climate had it? When did it pass away? How long was it since it had been destroyed?" He next spoke of the fish, especially of the herrings, larger than those of Loch Fyne, but not to be compared with the latter for flavour and delicacy; and then he said something of the bright genial climate and of the boon such a place was to the countless thousands of invalids who could not afford to leave home in search of those soft delicious lands where the breath of winter is unknown and where summer holds eternal sway. We may say that the elegance of the diction, the facility of expression, and the absence of notes, made the speech peculiarly un-English, and that it was, therefore, a departure from the ordinary beaten track, which merited the warm praise that other speakers gave it.

Mr. Scotter, the managing director of the London and South Western, speaking as one of the visitors, pointed out that a noble marine road, equal to any in Europe, might be made between the two piers, and that Bournemouth would then have charms which no other English watering-place could rival, and which would put it in the first rank among the Health Resorts of the World.

Knowing what Boscombe owes to Mr. McEwan Brown, and of what he is capable, we are sure that the suggestion will not be lost on him, and that he will not rest till the proposed marine road is carried through.

We believe that such a marine chain has long been thought of, and though we do not know whether anything is actually being done in the matter just now we have the conviction that before long the necessary arrangements will be made, and the work carried out triumphantly and to the advantage of the whole district.

The proceedings, favoured by brilliant skies and vast happy crowds, passed off without a hitch, and few of those who were present will ever forget the day. The duke made a graceful allusion to the sumptuous accommodation which had been provided for him at the Chine Hotel, and he added that he had never been more thoroughly at home, never better looked after; and he spoke from a long experience of hotels, both British and foreign. The luncheon was under the management of the proprietor of the same hotel, and we must add that it did great credit to all concerned, and was thoroughly enjoyed by the guests.

We do not profess to be prophets, but we shall be surprised if Boscombe does not rapidly grow at a still more rapid rate, and if before long many of the lovely sites still unoccupied have not been sold at the most enormous advance on their original cost.

ARSENIC AS A COSMETIC.

By G. Cadogan-Masterman, M.D.

During every trial for poisoning by arsenic now-a-days we are prepared to hear two stories in the evidence for the defence:—That of the Styrian arsenic eaters, and that it is used by ladies with rouge and pearl powder in the esoteric mysteries of the toilet. And both stories have been told so often and so impressively that not only the public, but the presumably well-informed narrators, have come to regard them as matters of indubitable fact. But they really stand in the same category as the tale of the Poison valley of Java, and the schoolboy legend that a little quicksilver put into a quill and deftly inserted into a dumpling will make the latter jump out of the pot! The valley never existed, and the experiment is believed in because it has never been tried.

The first is related on the sole authority of a certain Dr. von Tschudi, and appeared originally in *Le Journal de Chimie Médicale*, 1854, p. 445, and is to the effect that the peasantry of Styria and some parts of Hungary are in the habit of "eating arsenic," the men for the purpose of improving their wind as mountaineers, and the women for adding to their personal charms and plumpness. And he gives many examples which would be sufficiently convincing only it is perfectly clear from his description of the way in which the mineral is obtained, that, if they do eat it at all, it is some harmless substance, possibly an ore of zinc. And we know that there is no fact in therapeutics more certain that, so far from the human system becoming habituated to the use of arsenic, there is no remedy of which it is more intolerant. Even the usual medicinal dose of one-eighth of a grain daily is apt to disagree after a time, and the full dose of double that minute quantity can rarely be persisted in without poisonous effects compelling its intermission or disuse.

As for its employment as a cosmetic, no one out of a court of justice has ever heard of such a practice; bi-chloride of mercury is really the metallic base of all

face washes, such as Rowland's Kalydor, and so on; arsenic can only have been used by a person utterly ignorant of its effects, and who had, of course never used it before. It is desperately irritating even to the comparatively callous lining of the stomach, and far more so if applied either in powder or solution to the human skin. So dilute a lotion as would be produced by soaking a fly-paper in a pint of water would inflame it, and a somewhat stronger solution would quickly cover the face with angry pimples and rough excoriations, and its use as one of the most powerful and painful of escharotics is proof enough of this. The story of the German schoolgirls washing their plump cheeks with it is too absurd for serious refutation; but it is not difficult to trace how the myth arose, and we may put it into the form of a syllogism:—Diseases of the skin are very unsightly. Arsenic is used internally for the cure of these diseases. Therefore, arsenic applied to the healthy skin will make it more beautiful. The premises are sound, but the deduction is false, and yet with enough plausibility about it to make it popularly acceptable. I have noticed that the prolonged use of arsenic in small doses, ♏iij. *ter die*, produces a very unsightly brown staining of the skin, and a note to the same effect appeared in the *British Medical Journal* recently. And I have seen the hands and arms of sheep-washers inflamed from the same cause, although in South America I was astonished to see how little the hide-curers were affected by it; but in their case the profuse perspiration and their use of soap with it may have protected them.

In a trial which is still absorbing public attention, it seems a strange oversight that none of the medical witnesses pointed out that arsenic is never medicinally administered in powder, but in solution. The only exceptions to the latter form are the arseniates of soda and of iron, which are sometimes given in pill. In the long list of arsenical preparations collected by Jourdan (*Pharmacopée Universelle*) and by Dorvault (*La Botica*), chiefly coloured powders and pastes on the lines of *le powdre du frère côme*, to be used as escharotics, there is not one white powder nor one for internal use, with the exception, again, of the arseniate of soda, which is directed to be given in pill; the arseniate of iron, a green powder very rarely prescribed, is not referred to.

And it is hard to understand how any skilful advocate could have permitted that preposterous New York story to have been told of the sending to a chemist's for—was it half-a-dollar's worth?—of arsenic, and the putting of "a lump" of it into a cup of tea the victim was drinking! Oddly enough, however, it happens that, if the poison *could* have been bought at a dispensing chemist's in lumps, one might have been so treated and the beverage and the drinker been none the worse, if he had only left the fragment at the bottom of the teacup. Arsenious acid in the glacial form is so feebly soluble in astringent vegetable infusions, that very probably not an atom would have been taken up by the tea. In the stomach, even, large crystals, or at least pieces readily picked out, have been found, and yet the fluid therein has contained no trace of it.

The unfortunate and most unnecessary use of arseniate of soda in the making of fly-papers was probably suggested by the *Poudre aux mouches* or *Fliegengift*, a nearly black powder, obtained by exposing metallic arsenic to the air, which used to be much used on the continent for destroying insects, and has led to not a few fatal accidents and even murder amongst human beings. But, before the Maybrick trial, it is doubtful if one vendor in a hundred, and certainly one buyer in ten thousand, knew that those abominable papers did contain it; and the question is—how did the prisoner obtain that fatal knowledge, the tale of the school-girl confidences being a transparent fabrication and afterthought? At any rate their sale should be interdicted at once; for, as quassia is a most fatal poison to flies, and very attractive to them, whilst it is harmless to human beings, there is no need to use arsenic in any shape in their manufacture.

One evil result of the trial will be that von Tschudi's mischievous fable will be once more spread broadcast over the country, and it will be well to reproduce here Dr. A. S. Taylor's indignant criticism of the sensational and *banal* chapter in "Johnstone's Chemistry of Common Life," which first made it popular in England. It appears in the fourth edition of Pæreira's "Materia Medica," p. 702. "This absurd and incredible statement regarding the nutritious and beneficial properties of arsenic, has been lately revived and placed in an attractive form before the public by an English chemist. The question, however, is not one of chemistry, but of physiology and pathology; and in this point of view the so-called "undisputed facts" regarding the benefits derived from arsenic-eating have been rejected by all authors of repute. The publication of such a statement, unsupported as it is by those who have had ample and long experience on the subject of poisoning by arsenic, is only likely to be productive of great mischief. It may lead persons to take the course suggested in this book, and endeavour to fatten their children upon a substance which must ultimately destroy them; and it may justify burial-club murders by inducing people to believe that arsenic is given, not to kill, but to improve their personal appearance. Lastly, we may find that ingenious barristers, in defending prisoners, will adopt this author's theory in alleged cases of criminal poisoning by a woman or her paramour, that arsenic has been merely given as "a love awakener—the harbinger of happiness—the stimulator of ardent longings—the bestower of contentment and peace!" Now, was anything more infamously suggestive of crime, and the means of palliating or concealing it ever penned than this? Fortunately, however, there is no poison for which chemistry supplies such accurate and trace-reaching tests. With the fatal peculiarities that arsenic is tasteless, that it can be introduced in a hundred unsuspected ways into the victim's body, and that its effects simulate so closely the symptoms of disease, it is, indeed, providential that it can be detected by analysts so easily and with a certainty so absolute, and not by them only, but by those who have only the somewhat rudimentary knowledge of chemistry which is one of the characteristics of English medical men; and, as it can be most readily detected in the urine, the test can be applied without exciting the suspicion of the guilty, or offending the innocent.

There is a point, by the way, in the differentiation of the redness of the lining of the stomach in cases of suspected irritant poisoning, which deserves attention. One of the witnesses spoke of scattered spots of a deep red colour as characteristic of arsenical poisoning, and expressed surprise that they were not found. But these spots can only occur when the poison has been given in powder, and possibly a coarse one; each being the site of the lodgement of some fragment long enough to have acted as a caustic. When the arsenic is given in solution, as it clearly was in the above case, it would be unreasonable to look for them; for a diffused redness, brighter in colour than, but very similar to that produced by concentrated alcohol, could alone be induced.

THERAPEUTICAL NOTES.

From our Berlin Correspondent.

Creasote Treatment of Pulmonary Consumption—Chloralamid a New Hypnotic—Menthol in Skin Diseases—The Comparative Value of Hypnotics.

Prof. Dr. Sommerbrodt, of Breslau, publishes in the *Therapeutische Monatshefte* a further communication on the *Creasote Treatment of Pulmonary Consumption*. Since his last publication on the subject, in the autumn of 1887, he has continued to administer creasote in many hundreds of cases of pulmonary consumption. The drug was given in gelatine capsules, each of which contained one grain of creasote. He usually began by giving three capsules on the first day. Each following day, one more capsule was added to this dose until the daily amount (on the eighteenth day of treatment) consisted of twenty-one capsules, given at three times, equal to twenty-one grains of creasote. This large dose was uninterruptedly continued for many months. It is impossible to suppose that the twenty-one grains given on one day will, when the following dose is administered on the next day, completely have left the body. A cumulative effect of creasote during the treatment must therefore, he says, be inevitable, and he thinks it is quite possible that such a large quantity circulating in the blood may have a direct deleterious influence on the tubercle bacilli.

Sommerbrodt gives one striking example of the beneficial action of creasote. On the 30th of August, 1888, he began to treat a weak, sickly-looking lieutenant, who was suffering from extensive tubercular disease of the right lung, with the following symptoms: dulness over right apex above clavicle, dry crepitant râles, intense emaciation, distressing cough, moderate expectoration, loss of appetite. Bacilli and elastic fibres abundant in the sputum; slight dyspnœa. The patient had suffered from dry pleurisy one year previously.

On the 1st of September the creasote treatment commenced, and on the 18th of September the full dose of twenty capsules per day was reached. On the 29th of September the sputum examined microscopically showed elastic fibres and tubercle bacilli, which, however, entered only into the formation of small heaps. The other symptoms were much improved, the appetite being splendid. In the autumn the officer was enabled to resume his duties, and he was not once on the sick-list during the whole winter. He followed all the out-door drilling of his regiment, and had repeatedly to walk in snow, reaching up to his knees. His bodily weight steadily increased, gaining twenty pounds. He resumed a healthy appearance, and had no complaints whatever. In April, 1889, no physical signs of any lung disease could be detected on examination. During a period extending from the 1st of September, 1888, to commencement of June, 1889, he had swallowed 5,400 capsules, representing about nine ounces of creasote and thirty-five ounces of balsam of tolu. He never felt so well as he did after this treatment, which is still continued with a view of preventing recurrence. At present he takes only small doses—nine capsules per day.

The author treated many hundreds of cases with equal success, and was always, especially in recent cases, highly satisfied with this treatment. He therefore greatly advocates the new method, and strongly recommends the use of large doses. Small doses he considers quite inefficacious. Fifteen to twenty grains of creosote ought to form the daily dose, which should be continued for many months. It will, in most cases be found practicable to give such large doses. The method of administration he thinks is not essential, provided that the creosote is of first quality, and that it is always taken immediately after food. It may be given in the shape of capsules, drops, wine, or emulsion. Improvement of the patients symptoms should always form a fresh stimulus for continuance of the treatment.

Drs. Hagen and Hüfler report in the *M. Med. Wochenschift*, on the *hypnotic action of Chloralamid*. This drug belongs to the class of hypnotics which cause sleep a very short time after their administration, its effect being usually apparent within half an hour. The experiments with chloralamid were made on twenty-five patients, and three healthy people, altogether in twenty-eight cases. In twenty-six out of these cases a distinct hypnotic effect was obtained. The result was most excellent in sixteen cases; in the other cases it equalled the effect of other hypnotics; while in two cases it failed entirely. Chloralamid, according to the said authors, possesses the following advantages over chloral hydrate: its taste is more agreeable—it causes less ill-effects—adaptation to the remedy does not occur, and even after prolonged use of the drug its full action is usually developed.

With regard to the dosage, the authors found that in many cases, especially with women, thirty grains (in severer cases, forty-five grains) were sufficient. They were given in wine or in wafers.

The authors do not hesitate to declare that chloralamid is one of the most reliable hypnotics known. It consists of a white powder, readily soluble in water, of slightly bitter taste.

Saalfeld recommends *Menthol* as a local application in different affections of the skin, in which itching forms the most prominent symptom. He uses lotions, containing menthol, according to the following formula:

℞ Menthol ..... gr. 20
Spir. rectif..... ʒ ii.

Or ointments:

℞ Menthol ..... gr. 40
Ol. olivæ..... ʒ iii.
Lanolin .....ad. ʒ ii.
f. ungt.

In cases of scabies he uses the following prescription:

℞ Menthol ..... gr. 45
Bals. peru ..... ʒ iss.
Ungt. Wilson.
Lanolin .....āā ad. ʒ ii.
M. f. ungt.

Dr. Sastrowitz read a paper in the "Berlin Medical Society" on *Hypnotics*. He minutely studied the comparative value and indication of each of the different hypnotics, ancient and modern. His researches culminate in the following results:—

Chloral hydrate represents a most powerful hypnotic. Its action never fails, not even in cases where other similar drugs prove inefficacious. The administration of chloral hydrate, however, is not devoid of risk; large doses require great caution. They ought not to be given in cases of extensive disease of the lungs—as in acute pneumonia—and also not when the lungs are adherent to the thoracic wall or when any gross impediment exists in the respiratory organs. Chloral hydrate causes contraction of the pupils, and a state of excitation mostly occurs previous to the sleep. Both symptoms may fail to appear; in such cases further administration ought not to be undertaken. Smaller doses

of chloral hydrate are harmless, and may with perfect safety be given even in children's affections.

Paraldehyde, given in large doses, causes a number of symptoms similar to chronic alcoholism. It differs from alcohol in so far that it does not affect the heart. Adaptation to the drug, after continued use, is the rule; in such cases the daily dose has been increased up to three drachms without any ill effect. Paraldehyde is indicated in acute insomnia, and it acts specially beneficial when the latter is caused by intense itching of the skin. Paraldehyd is contra-indicated in all cases of bronchial affections.

Amylen hydrate is of very recent date, and yet it has already been outrun by sulfonal. It is a very safe hypnotic, being efficacious in acute as well as in chronic cases of insomnia. It is pretty harmless, one case being known where it was taken by mistake in a very considerable quantity without any disastrous effect, temporary state of intoxication being the only consequence. Dosage: ten to 100 grains. It is sometimes not well borne by the stomach, and in that case had better be applied per rectum.

Sulphonal has no disastrous effect on the heart. Its action is more gradual, sleep being effected within a few hours It has a specially beneficial influence in cases of motory excitation, as in chorea and mania. In the later disease sulphonal often causes a very quiet state, lasting for days if the drug is continued: excitation of sensory nerves and consequent insomnia is not so much benefited by it. Continued use of suphonal sometimes produces symptoms of giddiness and staggering gait. Sulphonal, according to the author, is indicated in all cases of acute insomnia where rapid action is not absolutely necessary, and in all cases of insomnia. Odourlessness and tastelessness of the preparation greatly facilitate its application.

Other modern hypnotics, *Urethan, Methylal, and Hypnon*, have already come to an early grave. They were either not devoid of danger, or their hypnotic effect could not be relied on. The author in comparing the effect of these different hypnotics, when given in the smallest possible dose, thinks that they have to be gauged according to the following list: Morphia, chloral hydrate, paraldehyde, sulphonal. When ranged according to their comparative harmlessness, and yet efficaciousness, they have to be enumerated in the following order: Chloral hydrate, sulphonal, amylen-hydrate, and morphia.

Reviews.

I.—*A Monograph of the British Uredineæ and Ustilagineæ.* By Charles B. Plowright, L.R.C.P., M.R.C.S., Senior Surgeon to the West Norfolk Hospital. Kegan Paul, Trench & Co., London.

II.—*Micro Fungi Britannici (Exsiccati)*. By Rev. J. E. Vize, M.A. J. E. Vize, Forden, Welchpool.

Mr. Plowright is a member of a rapidly-increasing class, and one deserving honour. Absorbed by the duties of a laborious and distracting profession, he finds time to study a branch of mycology demanding the study of a lifetime. He is favourably known at the Woolhope Club forays as well as in Sweden and countries even more remote, for his indefatigable researches in this vast field of natural history. As we turn over his beautifully printed and admirably illustrated pages and notice the scrupulous care with which the author has done his work, and then remember that all this erudition and observation appeals to only a small body of scientific men, we are overwhelmed with regret. The most feeble novel, the most puerile tract, would command fifty times as many readers, but such men as Mr. Plowright fight the battle of scientific progress and increase the joys of existence. Others amuse and tickle the fancy, and are thought very clever; but the patient scientific toiler plods on, happy in the feeling that he is, perhaps in ways little dreamt of, increasing human happiness, and learning something of those mysteries on which the health and food of millions depend. We could not here possibly do justice to the book. We can only say that anyone who will take the trouble to study Mr. Plowright's volume will find a perfect treasury of curious and trustworthy information. We dare not hope for a large sale, but the work will have a fit, though probably small circulation.

"Under the name of Hypodermieæ, De Bary unites the Uredineæ with the Ustilagineæ, which, however, do not seem to be very closely related to them." *(Sachs.)* Yet, related or not, they are well studied together, because whether viewed from the œconomic standpoint, or from the medical and scientific, their interest has much in common. Their œconomic interest arises from the fact that Mr. Plowright's pets are not of unstained character; they cause rust, and "bunt," and smut in wheat, and come before us with all the interest of freebooters; in fact the author introduces them as being "all parasites upon some living plant; in whatever part of the world phanerogams appear, these parasitic cryptogams accompany them." Among the misdeeds imputed to these entertaining miscreants is the production of alcohol (p. 15), which, however, is "not proven"; but after a trial comparable with that of Warren Hastings, they were found guilty of "blasting corn and English grain," the result being an Act of Parliament (of Massachusetts) specially levelled against them, the text of which is given by Mr. Plowright at p. 302, and is sufficiently curious. From the purely medical standpoint, the interest of these fungi lies in the fact that their study forms an admirable apprenticeship for the far severer study of those yet more abandoned characters, the Schizomycetes, which comprise the micrococci, bacilli, bacteria, and spirochætæ, which hold in animal pathology a place very similar to the one held in vegetable pathology by uredo and its congeners; for these latter have the advantage of presenting a fairly large multiple of μ in linear measurement, whereas the Schizomycetes are so minute as to elude all but the most skilful microscopists. Moreover the analogy of the uredine blights may furnish the clue to certain histological and developmental problems of the highest importance to the physician and surgeon. For example, it is still a question whether aborted organs and obsolete structures may not be stimulated by irritation into abnormal growth so as to resume somewhat of their former dimensions or even become the seat of cancerous tumours and similar morbid growths. Now the parallel of this actually happens in vegetable pathology under the irritation of a fungus. Lychnis diurna is normally dicœcious, each plant is either male or female, not both. But our own note book records "hermaphrodite lychnis diurna, with ten stamens shewing dark marone anthers at mouth of the tube; styles developed, half the height of the tube; abundance of seeds." In Mr. Plowright's book we find the explanation. He tells us (p. 79) that when the anthers of lychnis are attacked by ustilago violacea, the

female organs, normally aborted, are stimulated into full development. Compare with this the specimen of hop with both male and female flowers, the prunus padus bearing bladders instead of fruits, "probably due to a fungus," the fasciated stems of a thistle, the foliaceous flowers of a primrose and bean, and the various "altered plants," which are suggestively placed among the parasitic diseases in the teratological series of the Museum of the College of Surgeons. For analogies, almost like an incipient change of species, see Plowright, pp. 161 and 284, and 293 and 294. Yet again do we find that a true "amyloid degeneration," suggesting the so-called amyloid degeneration of animal pathology is produced by an æcidium, insomuch that the stems of a nettle are so swollen with starch that the Himalayan natives eat them much as we eat potatoes. Once more, the phenomena of alternate generation, of heterœcism, of polymorphism, may be seen writ large in the uredineæ, and they force the assumption that there must be parallel phenomena in the Schizomycetes; and if so, they account for the apparently erratic behavour of epidemics. The scientific interest, other than medical, of these fungi is also immense. As regards fertilisation by insects they deport themselves in much the same way as their floral superiors. The spermogonia secrete saccharine matter, and diffuse odours, whereby insects are attracted, and are made to disperse the spermatia. When produced on the upper surface of leaves the spermogonia make brilliantly coloured spots, yellow, orange, white and red; but when produced on the lower side of leaves the spots are made conspicuous to insects by a curious influence of the fungus which makes leaves, normally horizontal, stand up erect and expose their under surfaces.

It is very greatly to be hoped that this valuable and remunerative study will not be neglected now that Mr. Plowright and Mr. Vize have cleared the way. Whatever credit is due to Mr. Plowright is due also to Mr. Vise; for while the one supplies the written description of every British species, the other furnishes the beautifully mounted specimens by which those descriptions are illustrated. As a concluding effort to promote the study of these fungi, let us give a hint as to the easiest way to begin. Having read the half dozen pages in Sach's, proceed next to Plowright's four pages of glossary (p. 305.) Then by the aid of the plates (p. 324) familiarise the eye with these four structures, spermogonia, æcidia, uredospores, and teleutospores. Next, read chapter 12 (p. 105.) Then go through the book, referring frequently to a dozen or so of the slides which may be procured for illustration from Mr. Vize at Forden, Welshpool.

R. AUGUSTINE CHUDLEIGH, M.A.

Lectures on Nervous Diseases, from the Standpoint of Cerebral Localisation, and the Latest Methods employed in the Diagnosis and Treatment of these Affections. By AMBROSE RANNEY, A.M., M.D. (profusely illustrated). London and Philadelphia: F. A. Davis. 1889.

THIS is a veritable *edition de luxe.* The author (Dr. Ranney) professor of anatomy and physiology of the nervous system in the New York Post-Graduate School and Hospital, and professor of nervous and mental diseases in the medical department in the University of Vermont, has spared no pains in the production of the work. For the elucidation of his text, he has introduced most beautiful coloured original diagrams, sketches, photos, and he has been assisted by the publishers, who have reproduced in *fac simile* the results of his pencil. The letterpress is worthy of the illustrations, and it is seldom we meet with a work so admirably printed and so free from errata. So much for the typographical merits, let us examine its claims to consideration on other grounds. The work is divided into seven sections. The first section deals with the anatomical, physiological, and pathological deductions respecting the cerebro-spinal axis of man. This chapter opens with a short history of the famous American crowbar case, which Dr. Ranney says has been the starting-point of a new epoch in medical science. He explains how injuries of the brain (as by bullets) may not be attended by serious consequences, as the effects depend rather upon situation than upon severity. We have in this section a full description of the brain cells, the cerebral cortex, the nerve fibres, the corpus striatum, the optic thalamus, the capsular fibres of the cerebrum, the crus cerebri, the pons, the cerebellum, the medulla oblongata. After which we have a full description of the diagnostic value of the special symptoms of nervous derangement; and we have a *resumé* of some chapters which appeared in Dr. Ranney's work on "Surgical Diagnosis"; motor paralysis, cortical paralysis, hemiplegia, crossed paralysis, complete paralysis, sensory paralysis, hemi-anæsthesia, numbness and formication, hyperæsthesia, hæmocinopsia, aphasia, agraphia, word deafness, word blindness, are clearly defined, this being followed by general deductions relative to aphasia. Dr. Ranney then gives a summary of the diagnostic symptoms by which lesions of the brain may be localised during life; then a summary of the more important physiological and pathological facts pertaining to the spinal cord, concluding his first section with a summary of the cerebro-spinal architecture. This chapter is written in a most readable form, and it is accompanied by thirty-seven diagrams and sketches, coloured so as to bring out the more salient points and to explain the text. The reader is thus able to follow the author.

Section II. is entitled "Practical hints regarding the clinical examination of patients afflicted with nervous diseases, and the various tests which may be employed as aids in diagnosis." We would direct particular attention to part ii., "On the symptoms of nervous diseases revealed to the physician by his sense of sight." Dr. Ranney has very clearly exposed the importance of eye examination, and shown how necessary it is that the specialist should be something more than a specialist; the neurologist without an ophthalmoscope is like the mariner without a compass. Apart from the eye, special attention is directed to various other tests, and especially to the principles of electro-diagnosis.

Section III. deals with diseases of the brain and its envelopes. It is very exhaustive, and we need not enumerate all the special diseases which are very fully explained and illustrated.

Section IV. treats of diseases of the spinal cord and its envelopes, and is a very interesting and comprehensive treatise. "Functional nervous diseases" is the title of Section v., and here again the author brings to bear his knowledge of ophthalmology. He insists on the importance of the researches of Dr. Stevens, on the bearing of eye defect and eye strain in producing functional disorders. Chorea, for instance, Dr. Stevens found to be associated with hyperopia, and to be relieved by proper correction of the refractive errors. Dr. Ranney says: "I have looked care-

fully over the records of all cases of chorea which I have personally tested for anomalies of the visual apparatus; I have not found a single case where either manifest or latent hyperopia did not exist. . . . I have seen choreic symptoms disappear in several instances within a week or two when an existing hyperopia has been relieved by convex glasses, with frames well fitted to the child, so that each pupil is opposite the centre of the glass. It is not enough to tie a pair of glasses with frames made for an adult on to a child's head, and expect comfort to the child will follow such a procedure. Neither is it right to expect that glasses are all that is demanded when a child has esophasia, exophasia, or hyperphasia, in addition to hyperopia or hyperopic astigmatism, or refractive errors of the myopic type."

We mention this subject as we are not aware that English writers have attached much importance to it. The relief of headache by the proper correction of ocular defects is well known in English practice, and we believe that Dr. Brudenel Carter was one of the first to draw attention to this method of curing headache.

Section VI. deals with toxic and unclassified nervous diseases, and ranges over hydrophobia, multiple neuritis, chronic lead-poisoning, arsenic paralysis, alcoholism, acute and chronic mercurialism, bromism, tetanus, paralysis agitans, posterio lateral spinal sclerosis, exophthalmic goître, and myxœdema.

Section VII. gives an admirable account of the use of electricity in medicine, and a full description of electrical apparatus, illustrated with plates of the motor points.

The work concludes with a glossary, bibliography, and well-arranged index. We have given an outline of the scope and contents. Originally given in the form of lectures, and illustrated by drawings on the blackboard and coloured chalks, Dr. Renney has developed the various sections, bringing in the latest contributions to each special subject, and making not only a practical but a readable book. The value of a book of this kind to the general practitioner is as a work of reference; he is sure to have under treatment some form of nervous disease, and, without reading the whole book through, he can take it down and read up all that relates to the particular case he has in hand, it may be one of chorea, multiple neuritis, or sclerosis; he will benefit himself and his patient in this wise; knowing the latest views and the latest treatment, he will be armed. In process of time the whole work will be read.

English literature is enriched by a work of this kind, even though it is produced by an American house; and we may congratulate ourselves that we have in England such men as Ferrier, Hughlings-Jackson, who have paved the way for the better understanding of neurological problems, so that we may welcome in the spirit of friendly rivalry any additions to our knowledge, or means of acquiring it, which are placed within our reach by the enterprise of American publishers, though we cannot afford, even with our reputation, to rest upon our oars. Competition is productive of growth; a young people, and a reading people, give an encouragement to the production of works of this kind. The stimulus given to medical education by post-graduate lectures in America has led to a reproduction of the same kind of lectures in England, and we may reasonably anticipate that a similar stimulus will be given to book production by the beautiful volume which has been placed in the English market by Mr. F. A. Davis, of Philadelphia and London.

The Diseases of Children, Medical and Surgical. By Henry Ashby, M.D. Lond., M.R.C.P., Physician to the General Hospital for Sick Children, Manchester, etc.; and G. A. Wright, B.A., M.B. Oxon., F.R.C.S. Eng., Assistant-Surgeon to the Manchester Royal Infirmary, and Surgeon to the Children's Hospital. London: Longmans, Green and Co. 1889.

[Second Notice.]

The chapters on diseases of the digestive system include one on "Hernia," one on "Hare-lip," with other malformations, and conclude with chapter x. on "Diseases of the Liver and Spleen." Enlargement of the latter organ is chiefly treated of, and its association with the various cachexias and fevers of childhood. To determine enlargement of the spleen during illness, palpation rather than percussion is recommended, "as the lesser rigidity of the abdominal walls during early childhood usually readily permits of this (p. 146): it is effected by standing on the patient's right side and gently pressing two or three fingers of the right hand into the left hypochondrium beneath the costal arch, when the lower and inner edge of the spleen if enlarged can be readily felt as a movable tumour, which can be pressed upwards." We think deep percussion over the left lower ribs will often guide to the recognition of splenic enlargement, but agree with the authors, that if abnormal, the lower edge will extend below the costal arch. It is noted that enlarged retro-peritoneal glands have simulated enlarged spleen.

This tenth chapter, "Diseases of the Liver," begins: "In examining the liver of an infant or young child, it must be borne in mind that this organ is proportionately larger in the child than in the adult; it consequently occupies a greater space in the abdominal cavity, and thus to the inexperienced it may appear to be enlarged, when in reality it is only of normal size. The upper limit as determined by percussion (superficial dulness) reaches to the fifth space at the right edge of the sternum, to the upper border of the sixth rib in the nipple line, the seventh in the axillary and the ninth posteriorly, though the deep dulness reaches somewhat higher. While the edge of the right lobe does not in an adult extend below the costal arch in the recumbant position, in a child it always does. The size of the liver can be as readily estimated in a child as in an adult by percussion if the stomach is not over-distended; the lower edge can, however, be much more readily felt in a child than in an adult by placing the warm hand on the abdomen and gently pressing backwards and upwards. In most cases it can be easily determined if the edge is round or sharp or irregular." The child's liver is seldom reduced in size; acute atrophy is rare, and the cirrhosis of congenital syphilis may be found with either a small or a large liver. The liver is frequently enlarged, "due partly to its vascular nature, its veins being very readily distended, and partly also to the ready way in which it appears to store away fat."

"The best instance of its enlargement from mechanical causes is afforded by the congestion which so frequently attends heart disease, where, in consequence of regurgitation through the mitral valves, there is an obstruction to the onward flow of the blood." This sometimes excites a local disturbance, relieved by a mercurial aperient. The authors add: "There appears also often to be a temporary enlargement and a sluggish circulation in many cases of chronic intestinal catarrh, where there is said to be a functional derangement of the liver, accompanied by a loss of appetite

and pasty constipated stools deficient in bile, and an excess of pigment and perhaps uric acid in the urine. The liver is frequently enlarged from the presence of excess of fat; more rarely it is amyloid, or the seat of new growths, or abscess." Tuberculosis of the liver (p. 144) is said to be common, but rarely to cause any special symptoms; once, in a boy of fourteen years, local signs indicated large caseating tubercular abscesses. Hydatid cysts in the liver are rare before the sixth year. Multiple hepatic abscesses may occur as "the result of the absorption of some septic material from the region of the portal vein, or from some abscess in the immediate neighbourhood. . . . The symptoms consist in enlargement of the liver, extreme tendernesss, and intermittent fever. The prognosis is bad. If pus is found, it should be let out antiseptically." Here we may note some slight neglect of punctuation and polish, which a little care and attention on the part of either author would remove. The last sentence quoted might run: Pus, if found, should be evacuated antiseptically. Again, a direction, under "Swallowing foreign bodies," to avoid emetics, might be better put than "Emetics, as a rule, are not good treatment."

The marvellous advance of late years in the development of abdominal surgery is fully recognised in the work before us. The safe conduct in all that relates to operations in which the peritoneum is implicated, inaugurated by Sir Spencer Wells, is found to be as applicable to children as to adults. In this book, if the caution with which laparotomy is advised in cases of intussusception be extreme, there is no want of boldness in dealing with other accidents involving lesions of the peritoneum; exploratory incisions are fitly urged, and the free use of the aspirator, as in hydatid cysts, or of drainage tubes, is advocated. The whole subject of peritonitis in children is very ably handled; the authors, breaking loose from some tenets of their training at Guy's, and from dicta formulated there from the experiences of a general hospital rather than from institutions specially devoted to children's diseases, recognise in their district at Manchester evidence conclusive as to the existence of idiopathic peritonitis in children. This experience leaves the question of whether the peritoneum be as liable to become inflamed in children as in adults very much where it was, for if peritonitis in the adult be mostly secondary to some other lesions, so it is in children, but not exclusively so; after quoting Dr. West's case of idiopathic peritonitis, rapidly fatal to an infant of seven months old, we read: "Acute peritonitis occurs in older children by no means infrequently, often supervening in the midst of apparent health, and without cause, unless the effects of cold or of a more or less severe blow be accepted as such. At the *post-mortem* there is nothing to indicate where the inflammation commenced." Other cases are said to be secondary to tubercle, to a suppurating mesenteric gland, to ulcers of stomach, of ileum and vermiform appendix with or without perforation, to pleurisy and pericarditis, or an empyema bursting through the diaphragm; it is to be feared at the end of enteric fever, and is rare in the course of scarlet fever, "but it is not uncommon in the last stages of the succeeding nephritis, when uræmic phenomena have set in; it is then mostly of a purulent character. We have seen peritonitis *post-mortem* which appeared to have succeeded to or been associated with an acute intestinal catarrh, with symptoms of an inflammatory diarrhœa." Intussusception is also properly enumerated among the causes of acute peritonitis, though sometimes, as in the last mentioned case, the peritonitis is an integral part of the disease. A chronic peritonitis is comparatively common in children, and mostly tubercular; it may come on insidiously, even when generalised, but in no case, however limited, without rise of temperature, a diagnostic point where pain is a prominent symptom. Ascites not unfrequently results from this cause in children, during and after the second year of age, while in adults some form of portal obstruction is the commonest cause. The fluid may be slowly re-absorbed; in one case it was safely removed by capillary drainage. The conclusion come to is that "Chronic purulent peritonitis, whether tubercular or not, should be treated by incision and drainage, if the child's health is failing; and there is good evidence to show that not only may temporary relief be thus given, but long-lasting, if not permanent, recovery may take place as the result of incision." Even in acute purulent peritonitis it is important to provide an outlet for a localised abscess, to avoid if possible the fatal result of its rupture into the general peritoneal cavity. "Hence, as soon as it is clear that a local form of inflammation is not subsiding under medical treatment, the safest course is to carefully cut down upon and let out the matter. In perityphlitic abscess ('appendicular peritonitis'), when with fever, local pain, tenderness and induration and retraction of the leg no improvement takes place, an incision should be made just internal to the anterior superior spine of the ilium and the successive muscular layers divided until the neighbourhood of the abscess is made clear either by the sense of fluctuation, or by the œdematous condition of the tissues; a director is then thrust in the direction of the suspected cavity, and if pus appears the opening is enlarged with dressing forceps, and the cavity drained (p. 93). There is little danger in such an operation; even if no abscess is met with, and the peritoneal cavity is opened, no ill result is likely to follow, while the danger of rupture of an abscess into the general peritoneal cavity is very great." Whether an abscess be in the cellular tissue outside the peritoneum, or be really a local peritonitis, is of little importance, for in the latter case it would be circumscribed, and both need incision. In the case of a general purulent peritonitis, the authors say: "Should this already exist, the question of treatment is more uncertain, and the prospect far less hopeful; there is, however, little doubt that the right course is to open the abdomen, wash it out with some unirritating antiseptic, such as boracic lotion, and drain the peritonæum." Cases arise in which a counter opening is required, and here, with tubercular mischief, recovery is possible. Iliac abscesses generally do well after early opening of them. The three chapters devoted to the "Diseases of the Respiratory Apparatus" are sufficiently full, and thoroughly good; surgical intervention in pleurisy and empyema is adequately put, and the use of an exploratory needle, or the hypodermic syringe as a diagnostic aid, fairly allowed. The contrasted temperature charts of broncho-pneumonia and of acute lobar pneumonia at pp. 174 and 197 are useful; as also is one of a secondary pleuro-pneumonia and an empyema cured by incision. The sudden fall of temperature that marks the beginning of effusion in simple pleurisy is not noted, but the general course of pleurisy, with and without effusion, is correctly given.

Some exception may be taken to the arrangement by which bronchitis and its complications are separated from acute pneumonia, and especially to the latter being designated by the term "croupous." As a special seizure to which

children are liable, the distinction of acute lobar pneumonia from the more common lobular form cannot be too prominently brought forward; but the foreign name for it is a mistake; the absorbable, and often readily absorbed, exudation in the lung characteristic of this disease is in no sense croupous. Asthma and enlarged bronchial glands follow here; while laryngismus stridulus, and croup come at the beginning of these chapters, after some practical remarks on the physical examination of the chest in infants and children. Next to "child crowing" we have sections on spasmodic croup, or laryngitis stridulosa, also called false croup; on catarrhal laryngitis; on membranous croup, and on diphtheritic croup.

A table is given (p. 150) for the diagnosis of spasm of the glottis from spasmodic laryngitis, and from membranous croup, omitting catarrhal laryngitis; another column for this should be introduced under the head of catarrhal or inflammatory croup with these diagnostic points:—It occurs only in children; is worse in the very young; does not pass off in a few hours; the attack is attended with marked fever, and does not come on only at night. There is tracheitis and redness of the fauces, with perceptible enlargement of the small cervical and tracheal glands; though the dyspnœa may be great, the cough has a moist sound at times in the day, and the tendency is to recovery. The small lymphatic glands felt at the sides of the neck are to be found in simple membranous croup; the larger lymphatics at the angle of the jaw point to diphtheria or other specific fever. It is useful to know that the child has not been with others suffering from sore throat or infectious illness; in such cases no great precautions are needed in the family; moreover the hopes for the individual sufferer are not lost even if tracheotomy have to be faced. This is also the experience of the authors; they say (p. 151) "Children of all ages are liable to suffer from a catarrh of the larynx and trachea, though it is perhaps most common and is certainly most dangerous during the first two or three years of life. These attacks differ somewhat from those of spasmodic croup just described, inasmuch as there may be no violent exacerbation at night, yet in many cases all the symptoms are apt to be worse towards evening. They are mostly the result of cold, exposure to cold winds or a chill, and they may be associated with measles, either belonging to the premonitory symptoms or following the disappearance of the rash. The attacks are preceded for the most part by coryza, feverishness and cough, the first suspicious symptoms being the changed character of the cough, which is at first hard or hoarse, and then assumes the characteristic "croupy" or "brassy" character, which announces that there is some stenosis of the larynx. An examination of the fauces will probably show enlarged and congested tonsils with excessive secretion, and, if the epiglottis can be seen the mucous membrane will be found to be of a pinker colour than usual; but it is rarely possible to get a view of the larynx with the laryngoscope. As the symptoms become more marked, the air is heard to enter the larynx with a hissing sound, there is dyspnœa, the alæ nasi work, the chest falls in during inspiration, and there is often much distress. In some cases the child has to be propped up in bed, and pays no heed to its toys, its whole attention being taken up in the effort to breathe." It is further said that in membranous croup the signs of stenosis of the larynx are more marked and persistent than in catarrhal laryingitis, where, with frequent breathing and croupy cough, there are intervals of quiet, and "between whiles, and especially after a fit of coughing, the child is comparatively comfortable, and falls into an easy sleep. . . . On the other hand, the case may become so urgent that tracheotomy is repuired to stave off impending death, though usually the effects of treatment render this unnecessary. . . . The prognosis depends upon the diagnosis; if the case be one of catarrhal laryngitis, and the child is over two or three years of age, there is strong probability that it will recover. The younger child, the greater is the danger."

Membranous croup and diphtheritic croup are next discussed. Fibrinous exudations in the larynx are frequently diphtheritic; are they universally so? This question is negatived, and it is argued that such changes may result from local irritants, and from intense inflammation of many kinds; moreover, membranous laryngitis has been frequently observed by the authors in measles when no diphtheria was concerned, and occasionally as a complication both of enteric and scarlet fever. "One or two children in the same family may suffer from catarrhal laryngitis and bronchitis, while another may suffer from membranous croup, the attacks follow exposure to cold," p. 153. Attacks of influenza and of herpetic catarrh have also been so associated. But, while a fibrinous laryngitis may occur without the presence of diphtheria, it must be conceded that diphtheria is a frequent, if not the most frequent, cause of exuded fibrin. It should also be borne in mind that a laryngitis without membranous exudation may be excited by diphtheria and by other specific fevers, so that to speak of membranous and non-membranous croup as synonymous with zymotic or diphtheric and with simple croup is as wrong on general grounds as it would be in particular instances; the two terms rather point to a difference of degree found in both forms of the disease. Good evidence on this point comes from the Northern Convalescent Hospital for London at Winchmore Hill. Last year 3041 children, convalescent from scarlet fever, were under treatment; measles occurred early in the year to thirty of those children with four deaths, and whooping-cough to eighteen patients with two deaths; diphtheria occurred in twenty-seven cases, in eight cases this disease extended to the larynx, and all these ended fatally; of the remaining nineteen, two died. "There were, in addition, four cases of membranous croup, all of which died, and six cases of laryngeal obstruction without evidence of the formation of membrane, all of which recovered" (Met. Asyl. Board Report for 1888, p. 44). Four of the fatal cases and twelve recoveries occurred from March to August, seven of the deaths and five recoveries from October to December, at which time cases of diphtheria were received at the other district hospitals of the Asylum's Board; three of the four cases of membranous croup occurred early in the year, while measles was present; laryngitis, noted six times in July and August, is not a frequent complication of scarlet fever. The treatment, and all that is said and described of tracheotomy in the work before us, deserves our full acquiescence, except, perhaps, in one detail of nursing, the use of the steam-kettle. Both here and in the section on bronchitis too much stress is put upon this means of temporary relief. In cold climates, and in some houses where the sick room cannot be maintained at a right temperature, we may keep a warm atmosphere around the patient's bed by curtains and dry heat, when, as soon as the air is warmed enough, vapour will be absorbed from any moist surface or from atomised spray sufficient to make the

air easy of respiration; but steam in the air replaces so much of the oxygen, which dyspnœa is a struggle to gain, that the kettle should not be always kept going.

Diphtheria is treated of in chapter xv., here it is explicitly stated that no distinct membrane has appeared in cases where subsequent paralysis explained the nature of the original sore-throat. Again, exudation is seen on the tonsils in suddenly febrile seizures. They differ from diphtheria in "the less distinctly membranous character of the exudation, and the small tendency there is to involve the nasal mucous membrane and cervical glands" (p. 243). Difficulties of diagnosis probably lead to the opinion that diphtheria may recur many times, or that once having suffered, "does not protect, but appears to create a disposition for another attack" (p. 238). On the next page we read, "Mild cases occasionally occur in which the local lesions and general depression are slight. Membranous patches appear on the tonsils, but the nasal mucous membrane remains free, and there is no glandular swelling or albuminuria. Such patients are often running about with but little appearance of being ill, and the throat lesion may disappear in a few days. It is important to remember that in such cases paralysis may follow, or even a fatal result from cardiac failure." This is very true. We have also noticed that children who have passed through a slight attack with no other ill effects than a loss of power in the ciliary muscles for a time have escaped afterwards when exposed to infection. It would be interesting to know from those who are said to have had diphtheria many times how often any paralysis has followed. In the treatment too much is made of the view that the disease is local, though the directions given are such as are quite applicable to the malignant sore-throat of scarlet-fever, and such as materially aid the chances of recovery even when not carried out as effectually and thoroughly as desired. The use of pilocarpine on the first invasion of the larynx is not mentioned here, nor in the chapter on croup; it is given in the treatment of post-scarlatinal nephritis, p. 226, but is not referred to either in the index or appendix.

The chapters on "Diseases of the Circulatory System" include also congenital heart disease and nævus, both clearly set forth and illustrated. The section on pericarditis is of much interest. We quote (p. 274), by way of caution, a line on chronic pericardial effusion where a concurrent pleuritic effusion becomes absorbed, and adhesions form, while the pericardium remains distended with fluid. "If the child is seen for the first time when this has occurred an error in diagnosis is very easy, as the dulness caused by a distended pericardium shades away into the impared resonance given by a compressed and adherent left lung. We have several times seen in young children fluid aspirated from the pericardium by the needle passed into the axilla, when it was believed the fluid was being drawn from the left pleural cavity. In these cases the needle had passed through the compressed left lung and entered the distended pericardium." Effused fluid here is mostly reabsorbed; still the question of removing it has to be considered. Chorea has marked the ingress of pericarditis; rheumatism is mostly associated; tubercle is sometimes concerned.

Among the general diseases, a section on rheumatism occupies little more than two pages, but the part played by it is so fully described in other sections, notably in those on heart disease, on scarlet fever, and on chorea that some of the remarks under those heads will be noticed in connection with the short account given at p. 315. We there read: "Rheumatism, either in its acute or chronic form, is not common during the first four or five years of childhood; it is common after this age, but typical attacks of acute rheumatism occur less often in children than in young adults." Heredity, cold and damp, retained waste products in the blood, and the poison of scarlet fever, "seem in greater or less degree to predispose, or to excite an attack of rheumatism." Endocarditis is said, p. 280, to occur at all periods of life. "It may also occur during the two or three years succeeding birth; it is however less common at this period than in later life, though it is probably often overlooked. It is common during the later periods of childhood and youth. Like pericarditis, its usual association is with the rheumatic state, not that there is necessarily marked joint tenderness and high fever, but the patient exhibits some of the symptoms or associations of rheumatism, such as chorea, or erythema nodosum, or he has suffered from undoubted joint troubles in the past. During an attack of rheumatism, children are espcially prone to suffer from endocarditis, and the proportion of those who do suffer is greater than in the case of adults, being in the case of children perhaps 75—80 per cent.; in adults the proportion must be far less than this. Endocarditis also occurs in scarlatinal synovitis; the heart does not so often suffer here as in simple rheumatism." A child under two years of age is reported to have had articular rheumatism without high fever.

Anæmia follows most attacks. Children, like adults, are liable to relapses. It is the exception for children to escape endocarditis during acute rheumatism. We quote from p. 316; and further on: "It is a comparatively small matter if we are over-cautious in our treatment, in keeping at rest in bed a child who has but slight joint trouble and who appears to the friends to ail little; while it is a grave matter to allow a child who is suffering from incipient endocarditis to get up and run about, or to suffer one to contract endocarditis in consequence of getting up." Embolism may result from any form of endocarditis; hence a connection with one accident of heart disease and a form of hemiplegia to be considered in diseases of the nervous system. The connection of chorea, with rheumatism, is very close; the age of incidence corresponds; it is not common before the age of six years. In 252 cases fifteen were under six years, 102 from six to ten years, 135 from ten to fifteen years, 82 boys and 170 girls; the youngest child was a girl of four years of age (p. 397). Of these, forty-six are known to have had concurrent rheumatism; twenty more are said to have had rheumatic pains. In these cases "nothing abnormal was noticed in the heart's action in seventy-nine, in fifty-four there was irregularity or reduplication of the sounds, in 119 bruits, mostly heard at the apex more loudly than at the base, were detected. Some of those bruits were, no doubt, anæmic, inasmuch as they were present only at the base; it is seldom, however, possible to say dogmatically that a bruit heard during the course of chorea is simply hæmic, and it is necessary to have the patient some time under observation for a long period during convalescence before we are in a position to say if a so-called hæmic bruit is due to organic disease or not. It is well also to remember that endocarditis may occur, and yet no bruit be produced" (p. 401). It is in facts and remarks such as these that the great and special value of the book, in our opinion, consists.

Short Notices.

Strathpeffer Spa, its Climate and Waters. By Fortescue Fox, M.D., Lond. H. K. Lewis, 1889.

We are glad to welcome another contribution to the scanty literature of the British spas. The description given by Dr. Fortescue Fox leaves little to be desired; it is an invaluable little handbook, worthy of the attention of medical men who wish to know what manner of place it is to which they send their patients, and also likely to be of service to the visitors who require a guide on arrival at the spa. The sulphur and chalybeate waters must be very useful adjuncts to climatic treatment, and those who require bracing air may well weigh the advantages which Strathpeffer affords before accepting the alternative of a long journey to a foreign spa.

R. Shingleton Smith.

The Mechanism of the Circulation of the Blood through Organically Diseased Hearts. By Herbert Davies, M.D., F.R.C.P. London: H. K. Lewis, 1889.

These papers, the work of the late Dr. Herbert Davies, edited by his son, Dr. Arthur Templer Davies, are the result of many years' careful study and matured thought on a subject in which he took the most profound and deep interest. Their object is to investigate the mechanical conditions in the working of the diseased heart in accordance with the established fundamental laws relating to the physiological mode of working of the healthy heart, consisting of its two functionally distinct and perfect muscular organs, provided with their respective valvular appliances, and performing very unequal physical tasks. These laws are:—1. The corresponding chambers of the right and left hearts receive and expel their contents exactly synchronously, respectively, the two auricles contracting in unison and dilating in unison, and the two ventricles exhibiting, respectively, synchronous action in their systole, as well as diastole; and, 2. Equal volumes of blood pass, in equally and the same time, through any two corresponding orifices of the heart. These two principles are applied to the different forms of valvular disease, and various interesting facts are deduced. No abstract is possible; the book is a small one, and cannot be still further condensed.

L'Atonie Intestinal et ses Complications. By Dr. Ch. Malibran. Paris, 1889.

This is an interesting work, Dr. Malibran having had special opportunities of observing the diseases of the digestive canal, owing to his practice being at one of the thermal stations, which has a great reputation for the treatment of intestinal affections. He believes that the majority of these affections have a common root in intestinal atony. Patients who had submitted to a variety of treatment for affections variously diagnosed as constipation, pseudo-membranous enteritis, enteralgia, intestinal rheumatism, typhlitis, colitis, intestinal dyspepsia, etc., were all thought by Dr. Malibran to be suffering from intestinal atony with other complications, capable of satisfactorily explaining the sequence of morbid phenomena. He divides the causes into three groups: insufficiency of sensitive impressions, of nervous motor action, and of contractility; the last including organic and functional insufficiency. It is the most frequent form in which atony is engendered, whether by excess of contraction, excess of tension, or by paralysis. The author divides the complications into mechanical or irritative, and infectious. The clinical study of these disorders is very ably discussed, and the therapeutics are given in greater detail than is usual in works of this kind. The work is especially useful to the general practitioner. H. R. H.

Les Agents Paovocateurs de L'Hysterie. By Georges Guinon, 1889.

This work has been compiled under the immediate supervision of Professor Charcot, and is devoted to the study of the exciting causes of hysteria, and their influence on the different modes in which the neurosis is developed. The first part is exclusively clinical, and contains many references to ancient authors who had recognised many of the provocative agents, but entirely failed to correctly estimate others. The exciting causes are thus classified: *Moral emotions* (attempted hypnotism, nervous shock, earthquakes, traumatism, thunderclap, etc.); *general and infectious diseases* (typhoid fever, pneumonia, scarlet fever, rheumatic fever, diabetes, malaria, syphilis); morbid conditions, characterised by great debility (hæmorrhages, overwork, mental or physical, onanism, venereal excess, anœmia, and chlorosis); *Intoxication* (chronic, such as lead, alcohol, mercury, sulphuretted carbon, or acute, such as by chloroform); *diseases of the genital apparatus, and diseases of the nervous system* (sclerosis, tabes dorsalis, Friedreich's disease, etc.). This list is far from being exhaustive, as many exciting causes are only occasionally harmful, and not specific. The second part of the work treats of these occasional causes, and great pains are taken to establish in each case that the disease is true hysteria. It is admitted that the same exciting causes which produce hysteria may also give rise to other nervous troubles, and especially to neurasthenia, the combination of which with hysteria has led to much confusion in nosography. This combination of different affections due to the same causes is easily understood, when it is considered that the exciting causes are of a commonplace character, although only occasionally harmful. The exciting cause however often determines the distinctive character or peculiarities of the neurosis. The bibliographical researches in Mr. Guinon's work are very extensive, and the whole book is written under the inspiration of Professor Charcot; it throws an important light on the essence of the disease known as hysteria, and not merely on the varied phases which the hysterical neurosis may assume. H. R. H.

Hemiplégie Syphilitique. By Professor Pitres.

This is a good clear exposition of our present knowledge of cerebral syphilis. Professor Pitres has gathered together eight cases of hemiplegia, following syphilis of from one to fifteen years' duration. After recapitulating the lesions which cause this affection, the professor goes on to show what are the premonitory symptoms, and attaches most importance to simultaneous vomiting and headache, the latter being deep-seated, intra-cranial, violent, obstinate, and aggravated towards night. The work concludes with the diagnosis and treatment, which if commenced early will obviate many of the graver symptoms. H. R. H.

The Provincial Medical Journal,

SEPTEMBER, 1889.

THIS trial, remarkable in every respect, will form an important precedent in medico-legal cases. It appears to us as almost puerile to dwell on the discrepancy in the medical evidence; it is no more remarkable than the fact that Sir CHARLES RUSSELL was engaged for the defence, and Mr. ADDISON for the prosecution. The learned counsel on both sides presented the case in all its bearings, as they looked at the facts and interpreted them, and we believe that both Sir CHARLES RUSSELL and Mr. ADDISON were actuated by similar influences—a desire that justice should be done. The bar surely exists for this purpose alone, and not simply for the display of forensic eloquence, or for the escape of a criminal by the aid of technical loopholes. We say this in all faith, for the medical profession does not fling stones at the profession which gave rise to the saying "that doctors disagree." The commentary of Justice STEPHEN on the case, so far as the medical evidence was concerned, strikes us as being conceived in a narrow view of thought, and as unworthy of the best traditions of the bench; whilst his remarks about a doctor and drugs was really a misquotation. It was an "apothecary" who was defined as a person who poured drugs about which he knew little, into a body about which he knew less. An apothecary and a doctor are very different personages; but we may pass over without further comment all these ungenerous allusions to the profession in the judge's charge. Judge STEPHEN, happily as yet, has not required any serious medical attendance; when he does require medical aid, and when he has thrown his life into the hands of some eminent practitioner, he will then value the aid he will receive, and will probably alter his opinion, "that an hour is a long time for a medical consultation;" and he will, moreover, find that the personal sympathy of his medical attendant, and skill, will be factors about which he will have a much higher conception.

The medico-legal aspects of this painful domestic tragedy concern every member of the profession. The poison arsenic is one commonly sold, rendering itself readily to the poisoner. We may at any moment be placed in the same position as the Liverpool medical men. The symptoms of acute and chronic arsenic poisoning are very faithfully described in our text-books, and the differentiation between the *post-mortem* appearances of arsenical poisoning and disease is clearly made out. In text-books, however, the authors are tied down: they can only give general symptoms; they cannot extend their matter, and detail those departures from the ordinary types, which occur in connection with almost every case of poisoning; so that the absence of several prominent symptoms does not invalidate the view that Mr. MAYBRICK died from arsenical poisoning. The evidence for the prosecution was overwhelming; the presence of arsenic in the body, *post-mortem*, the symptoms, all pointed to this agent as the exciting cause of the gastro-enteritis which existed. The absence of certain symptoms did not weaken the evidence. In many diseases we do not have all the classical symptoms; but we have, as a rule, sufficient to account for the phenomena, and to classify the disease. The answer to the question given by the defence: "If not arsenic, what caused the gastro-enteritis?" did not satisfy us. "Could cold cause it?" This was suggested by a very eminent Dublin practitioner; but we hardly think this view will find many adherents. Dr. TIDY, though he denied the theory of arsenical poisoning, yet could not suggest, in answer to Mr. ADDISON, any cause for the gastro-enteritis, and here he strengthened the case for the prosecution. Here are Dr. TIDY'S words:

"I cannot suggest what caused his death, and cannot suggest what substance it was which acted on him as an irritant. The sickness was not like that of arsenic."

It is clear that the sickness was not like that of arsenic, as described in our text-books; but we believe that some of our text-books state that symptoms vary. Even HUSBAND'S elementary book says: "Certain anomalies may occur. The pain may be absent or but slight. Vomiting and purging do not occur in all cases; nor is thirst—a most persistent symptom—always present. . . ." Dr. TIDY may have made to himself a mental reservation as to the nature of the symptoms differing from the classical symptoms, hence his position in the witness-box. Any number of negatives could hardly weaken the evidence of Dr. STEPHENSON, in view of the finding of arsenic in the liver, and the symptoms there were of gastro-enteritis, plus some of the symptoms of arsenical poisoning observed during life, and substantiated by the evidence of medical men who were in attendance during life. The medical aspects of the case have no relation to the question of motive, or to the moral sides of this great trial. Even the presence of such a quantity of arsenic in the house—in bottles, in handkerchiefs—had not to be taken into account by the medical experts for the prosecution.

But all these points had to be considered by the jury, and as the judge laid down, they were not to look upon it from a medical or a chemical side, but from a general point, taking into consideration her lettters, her statement, the motive that may have influenced her; all the facts which were brought out in the course of the trial. The verdict was in full accord with the evidence, and however painful it may be to bring in a verdict of guilty, the jury faithfully discharged their duty.

IN writing on Cambridge there are many difficulties, owing to the wealth of material which forces itself on the writer, even though he may not have made a particular study of the subject; but the chief difficulty lies in attempting to do justice to so large a subject in a compass so narrow as that of the following article. There has always existed a good deal of what may be called the criticism of comparison between Oxford and Cambridge: their respective excellencies in learning, teaching, architecture, and athletics are

pretty widely, and even acrimoniously, discussed. The most striking phase of the modern development of Cambridge is the great prosperity and rapid growth of its natural science and medical side, in which it has shot far ahead of Oxford, though perhaps it may not have advanced at an equal pace with the sister university in studies of a kind which may be said to appeal less to the practical side of life. Comparisons between the actual towns have been made in the greatest abundance; perhaps the least obvious one is the best—namely, that "Cambridge is more grandiose, while Oxford is more grand." This, though it may not satisfy a purely mathematical mind, is on the whole fair, if obscure. Cambridge has not been well off for appreciation; people take it too much as a matter of course. If the University were wise, it might be induced to appoint a body of admiring and æsthetically-minded Americans (preferably Bostonians) to act as guides and instructors to a large body of its graduates and undergraduates, who would then be enabled in turn to diffuse to the outer world a leavening of the knowledge of its manifold and indeed innumerable charms. Situated as it is in a country created with no exaggerated beauties, it has been unfairly taxed with its natural flatness, because the neighbourhood has no imposing rocks or hills to give it claims to orthodox and obvious picturesqueness; indeed, the Cam itself above the town is nothing but a charming brook. Cambridge can boast of having educated a long line of poets in succession, the list beginning with Chaucer, and ending with Byron and Tennyson; yet none of them seem to have found any great inspiration in its exquisite stretches of lush-green water-meadows; its marshes aflame with yellow marigolds, and gemmed with the orchid-like blossoms of the sagittaria, through which willow-fringed streams wind slowly, among groups of poplars. The charm of such landscape may after all be more apparent to the painter than the poet, as it lies lightly wrapped in mist, or bathed in sunlight, waiting for a fresh Corot or Cuyp to lovingly paint it.

There have been two ancient Roman settlements, either of which may have been the origin of the modern town of Cambridge: one round the Castle Hill (itself an ancient British defence), and the other at Grantchester, of more former importance, and higher up the Cam. Indeed, the fields between Cambridge and Grantchester have been covered with Roman villas, and the plough continually laid bare their foundations as late as the sixteenth century. A castle was probably built during the Danish wars, when the town suffered much, having been plundered and burnt in 871, and eight years later formed the headquarters of the three Danish Kings—Guthrum, Oskytel, and Anwind, who laid waste this side of England with their army. Some years later the Cambridgeshire men made a good stand against the Danes, and earned for themselves fame in Saxon story; but their efforts were vain, and the country was ravaged again, and the town burnt in 1010. This stormy history continues after the Norman Conquest, during the struggle between the Normans and the Saxon patriots, who had taken refuge in the fens of Ely and Lincolnshire; for the next two centuries the military importance of Cambridge continued, as a rallying-point against the turbulent and rebellious Barons who took continual refuge in the Isle of Ely. Immediately on the death of King John, Louis (the Dauphin of France) came over and held a council with the Barons at Cambridge, intending to become their leader; in fact, all through these early times the place had a most stormy existence. In the fourteenth century the Castle was still being kept in good repair, and we find Edward III. granting lands in the county, by the tenure "of holding the King's curry-comb at whatever hour the King should mount his palfrey at the Castle of Cambridge." The civil troubles of the seventeenth century again affected the town when it became Cromwell's "prime garrison" in 1642, and the Castle Magazine was seized; the Castle itself must by this time have been in a ruinous state, as Camden, in his "Britannia" (1555), speaks of it as "a large antient Castle, which seems now to have lived out its full time." These few historic facts curiously exemplify how the history of every ancient town in England is very nearly identical with that of the country at large.

Of the different colleges it is impossible here to give the barest outline of their origin and growth, however interesting it would be to an antiquary; but much may be seen "writ large" in the various styles and periods of their architecture and ornaments, which comprise additions by every generation. By far the noblest building in Cambridge is the Chapel of Kings College, a perfect piece of architecture (designed for Henry IV., the founder of the college), which for beauty even excels such buildings as Henry the Seventh's Chapel, Westminster, or Saint George's Chapel, Windsor. It is probably the best known building in England, and fills everyone with delight, except unfortunately Mr. Ruskin, who is said to have likened it to a billiard table, with its legs in the air; Wordsworth seems here a better art critic than the Sage of Coniston, and in his fine sonnet on it has spoken beautifully of it as "the glorious work of fine intelligence." The chapel is the only part of the King's original most sumptuous design that was completed, and it must ever be borne in mind that the original designer intended to break the sky-line, now so uniform, with a lofty gate-house and a loftier bell-tower, and that it was built to be only a college chapel. In every aspect it is lovely, whether by sunshine or moon-light, from near or afar, seeming to spring from the green turf with the spontaneity of a flower and a lily-like purity. The interior is superb; the windows, which are its leading architectural feature, are filled with the finest old glass, rich in symbolic type and anti-type. As the sunshine streams through them, lighting up on its passage (in the language of the old Deed in which they were contracted for), the "perfyt glasse and oryent colours and imagery of the story of ye old lawe and ye new lawe," filling the air with mysteries of coloured shade, and forming a glorious atmosphere through which to gaze at that roof of fretted stone, seeming lighter than wood

and more delicate than ivory carving, and those walls royally blazoned, the conviction is forced on us that here at least we have absolute perfection defying criticism. King's is the first of the series of adjoining colleges which stretch their lawns down to the Cam, and form "The Backs;" the river is here a pure, winding stream of ornamental water, forming a mirror for green sward, stately lime trees, and Palladian bridges. Clare College comes next to King's, and its "rococco" architecture forms a grating contrast to the neighbouring Royal Chapel, and the beautiful unfinished fifteenth century gate of King's; however Clare is lovely in autumn, when the creeper covering the hall fills the whole of one court with a scarlet glory of colour. Passing along the "Backs," next comes Trinity, now the vastest college in the university, and possesses the best college library, the windows of which command the choicest views of turf, trees, and waters, in Cambridge. Entering from the street, and passing under the glorious entrance gate, covered with the arms of kings and princes, in the midst of which is a statue of Henry VIII., you face the hall and chapel. This is the "great court," and in its centre is a beautiful, ever-flowing fountain. The chapel is not specially fine, but is one of the few known edifices of Queen Mary's reign: the hall itself is, within and without, as beautiful a specimen of mediæval work as can be seen. Passing between the master's lodge and the hall, one reaches Neville's Court (built by the master bearing that name); it has a beautiful Renaissance Tribune facing the stately library, and is surrounded by an arcade of delicate proportions, with arches of harmonious curve. The mixture of styles in Trinity has its charms, and does but echo the widely differing characters of its most illustrious sons, among whom are such as Bacon and Byron, Whewell and Macaulay. Tennyson often must have strolled under that "long walk of limes" with Arthur Hallam, never dreaming he would one day have to revisit alone this scene of their perfect friendship "to see the rooms in which he dwelt" and turn in sorrow away . . . . . "Another name was on the door." It is a curious coincidence that two of our greatest poets, both Cambridge men, should each, by the untimely loss of a college friend, have added to the treasures of our literature two such poems as "Lycidas" and "In Memoriam"; each differs in form and expression completely, but both strike the same real note of sorrow. It would be pleasant to have space to treat each college in detail, but to give a mere catalogue of the illustrious men which each has at some time held in its walls would make in itself a work, formidable in length. We must go through the stately modern part of John's, rather severe in the accuracy of modern Gothic, across its covered bridge, which bears a likeness to the Venetian "Bridge of Sighs," and reach its old courts of time-stained brick, in the Tudor style of Hampton Court, they are quaint but depressing, and the Chapel, which is modern, in spite of its fine tower, is inharmonious and aggressive in outline, and its stone neither contrasts nor harmonises with the Tudor brickwork. To go back more to the centre of the town, noticing the University Church, Great Saint Mary's, and the continental-looking market place behind it, and, turning down the lane near the Senate House, leads one to the "Gate of Honour," one entrance to Caius' College, with its memories of its great benefactor and part-founder, the scholar and antiquary, the physician to Queens Mary and Elizabeth. Dr. Caius so added to and endowed his own old College, Gonville Hall, that he gave his own name in addition to it. This has been, and is still, the essentially medical college of Cambridge, and out of that old "Gate of Honour" Harvey, the discoverer of the circulation of the blood, must have passed; the epitaph of the founder on his tomb in the College Chapel is pathetic in brevity, "Caius fui." Quite away in the fields lies Jesus' College, clustered around and comprising the old Nunnery of Saint Rhadegunde; it has a distinctive character with its noble old chapel dimly lighted up with fine glass, by Morris, and its solemn cloistered court brooding under the shadow of the old four-square tower. Singularly beautiful, too, are its three-sided courts and lofty turretted gateway of warmly tinted ruddy brick, wreathed with ivy, and festooned with the faint lavender-coloured blossoms of the wisteria; but above all praise is the view from these courts across to the distant colleges with their towers and pinnacles peeping out among the ancient limes and elms. Much might be said of other colleges, including Christ's, with its memories of Milton and his ancient mulberry tree; a coeval of the Stratford-on-Avon tree, which grew in Shakespeare's garden till the last century, and relics made from which were treasured by Garrick. Peterhouse, the original College of Gray, whose window still shows the iron bar fastened there to aid the timid poet's escape in case of fire. Pembroke, opposite to Peterhouse, the College of William Pitt, and the tranquil abode of Gray's later years, and where he died; he left an ample monument to fame in his "Elegy," and his own charming letters; his was a fastidious over-refined nature, and essentially not of the eighteenth century. One smiles and seems to know the poet better on reading his generous will and the enviable bequest to his second cousin, Anna, Lady Goring, of "a pair of large blue and white old Japan China Jars." Then there is Magdalen, with old Samuel Pepys, the diarist, as tutelary god and its pretty brick river-front, and the Pepysian Library, abounding in rare prints and the rarest of old broad-side ballads. Then there is Sidney Sussex, with its Cromwellian associations and Emmanuel of Puritan memory; this last, the College of Harvard, who carried the traditions of Cambridge away to the New World.

Downing College must not be omitted, with its buildings of a style once favoured for county lunatic asylums, but its fellows' gardens are pretty, and contain good trees. Away in a bleak spot out of Cambridge lies desolate Cavendish, looking like a half-finished railway hotel. On the other side of the town is Selwyn, unfinished as yet, but what is built, clerically handsome, with red brick and white stone. Between Selwyn and Cambridge is Newnham, of which, and Girton, no

profane male may speak with authority; outwardly they are pleasing, and of brick. Such are just the barest skeleton outlines of some aspects of Cambridge and its colleges. To complete the picture, add in many students flying about in the morning in cap and gown from lecture to lecture. In the afternoon the same busy forms, only now clad in coats of many colours ("blazers"), are rushing off to tennis, to the river, or to cricket, or whatever other game you can imagine, filling the old courts, streets, and lanes with life and motion. To judge from externals, Young England, as seen at Cambridge, is a bright, cheerful, healthy collection of young men, apparently unmindful of the sad seriousness of life, untouched by the "welt-schmerz," and not likely to develop into fresh examples of the "Robert Elsmere" type.

W. Armstrong Willis.

The laymen who had the fortune to hear the address of the President of the British Medical Association would be able to fully appreciate the point of the story told by Sir James Kitson at the dinner of the British Medical Association, and we believe that the story would never have been told or even originated had it not been for Mr. Wheelhouse's address. A lady staying at Sir James Kitson's was introduced to another guest, and with the privilege allowed to her charming sex, she asked, "I presume you are a young doctor?" "Yes," was the reply. "Ah, then you have not had time," she replied, "to do much harm." The profession, so ready to smile at jokes directed against medicine, received this chestnut with full appreciation of the humour; but Mr. Wheelhouse really inspired the joke by his elaborate description of the ignorance of the average young qualified practitioner. We expect a plentiful crop of this class of tale; we also expect leaders and paragraphs on the folly of trusting the public health to men of whom their own leaders can so speak in public, and certainly we cannot use many arguments in favour of the qualified against the unqualified with any degree of logical consistency when a member of the Council of Medical Education can on a public platform so openly expose our system of medical examination. It may be a grave question as to the truth of Mr. Wheelhouse's description, but, unfortunately, it is not Mr. Wheelhouse we have to deal with, but the President of the British Medical Association; he is now invested with a degree of importance which places him on a much higher level than that of a general practitioner; his words will be quoted and quoted, and what may be only an individual opinion based on error, becomes in the President of the British Medical Association an authoritative utterance. We question very much the wisdom of ventilating the grievances and the defects of the profession before a public audience. If discussion could have followed on the paper then, some justification could be found for introducing such controversial and defamatory matter.

If reform could even be obtained in this way, we could understand why the subject was introduced; but seeing that the question of examination rests with the Medical Council, seeing that we have organs for the discussion of medical matters, we fail to see any advantage from washing our dirty linen in public. It is right and just that if the system of medical education be as imperfect as Mr. Wheelhouse asserts it to be, that it should be remedied; but as we know, there are two sides of the question, and we have so far only heard, and the public will only hear, one side. A popular audience, partly medical, partly lay, heard the address; the columns of the lay press carried it next day over England, and we can imagine how at the present time when medical science is sneered at over the Maybrick case, the words of the President will be quoted as justifying the popular prejudices against medicine. The young practitioner is not fairly treated. He is innocent, for he has complied with the regulations laid down by the Council, upon whom rests any blame. We are astonished that such an *astute* practitioner as Mr. Wheelhouse should have chosen such a subject for his address, but Homer sometimes nods, and one of our shrewdest general practitioners may sometimes even make a mistake. It is more complimentary to Mr. Wheelhouse to honestly criticise his address than to pour on it the fulsome flattery which is annually poured on the readers of addresses in the editorial columns of the *British Medical Journal*. These stereotyped phases of compliment, we would almost suspect, are kept in stock, and with a little change they appear from each year appended to each presidential address—a custom certainly more honoured in the breach than in the observance. Whatever we may think of the subject of the address, we can only have one opinion as to the form in which it was conveyed. With a clear enunciation, and in language aptly chosen, and occasionally rising to eloquence, Mr. Wheelhouse strove to interest his auditors, who could follow his arguments and his periods without straining their ears—a pleasure not always experienced at presidential addresses.

The great capacity of Mr. Wheelhouse, perhaps, made us all the more disappointed with his subject-matter. We, knowing his surgical skill, hoped for some original contribution, something beyond old wine in a new bottle, for after all this question of examination and pupilage is threshed out in the old journals almost on the same lines as in the address; something, in a word, that would add to the fame of the Leeds School of Medicine, and something that would live to Mr. Wheelhouse's credit.

We commenced this article with a story and we finish it with another. The moral lies in the last line. "If you will permit me to say so, doctor," remarked the patient, "Science has in you one of its most persevering disciples." The doctor's face expressed the gratification the compliment gave him, and the patient continued, "But I have one favour to ask of you." "Name it," said the pleased and smiling Galen. "You have treated me scientifically for six weeks." "Yes." "Well, give me something to get well on."

"*Point de Zele*," said TALLEYRAND to a youthful aspirant for office. Dr. BALLARD re-echoes the advice of the old French politician to the young medical officers of health, who may feel impatient at the restraints imposed on them by ignorance, stupidity, and cupidity. Youth is the time for generous impulses. The young practitioner, seeing death following on neglect of sanitation, feels indignant that steps should not be at once taken to arrest disease, and he expresses his opinion. He wants something done, and done quickly; but in his way stand prejudice, obstacles in the shape of red-tape, and feeling his powerlessness, he gives vent to some expressions, and then he is doomed. His impatience to do good is a grievous fault. He should not excite himself over his work: he should have a share of the "tact" which is so possessed by the Board to which he is health officer, and this tact, called by another name, is "masterly inactivity." We certainly are of opinion that the virtue of tact is very largely possessed by medical officers of health; and if this qualification were not possessed, there would be few medical officers of health of long standing, or of long tenure of office. We can trace the influence of tact over geographical areas, and we could give a coloured chart of certain towns where tact and masterly inactivity were synonymous.

The words of warning uttered by Dr. BALLARD will have a due effect on the holders of health appointments; and if long tenure of office be the end in view, by the observance of the rules laid down by one who is a veritable NESTOR in the public service, permanency of tenure will be secured. But Dr. BALLARD, though he advises tact, though he encourages young men to bear patiently the snubs and insults they will receive, yet does not, we trust, desire his advice to be taken in too literal a sense. Knowledge comes before tact, and he has told us in his very practical address what the requisites are for an efficient medical officer of health. With knowledge and with tact the medical officer of health will be able to guide the public health; and as tact comes from long training, we may look hopefully to the future, even though a few go down in the struggle during the years of patient endurance, "which patient merit from the unworthy takes." The medical officer of health is not an admistrator, he is an adviser. These are weighty words, and should be remembered. Dr. GOLDIE, of Leeds, for sixteen years was medical officer of health for Leeds. It took the Sanitary Committee sixteen years to find out his, shall we call it inefficiency; yet the Mayor of Leeds, at his speech at the banquet of the British Medical Association, pointed out in terms of pride the successful results obtained during Dr. GOLDIE'S administration. Had Dr. GOLDIE possessed a very small degree of tact, he might still be medical officer of health for Leeds; for he would have been able to smooth over the little difficulties which led to his resignation. It is very evident, from the evidence which led to his resignation, that he tried to be an administrator as well as an adviser, and he might have spared himself much anxiety and trouble by confining himself purely to advisiorial work, throwing on the sanitary inspectors all the detail of administration.

Dr. HIME, of Bradford, affords us another instance of the want of tact. There can be no question of Dr. HIME'S capacity, or of his educational position; yet he was sacrificed, because he did not possess this needful qualification—the art of humouring the Sanitary Committee. All this seems very pitiful, but how true it is. The medical officer of health, says Dr. BALLARD, must have "that acquisition of rare value, tact, the possession or lack of which might make all the difference between the *successful* and the inefficient medical officer of health. Deficiency in tact was a fault chiefly observable amongst the junior members of the confraternity. Anxious to serve their district, earnest and enthusiastic, they chafed at obstacles which they found impenetrable, and were ready to give up a strife, which over and over again terminated in their discomfiture. It was men of this stamp (and they were not always—he said it with bated breath—young men) that he heard perpetually calling out for central interference. They forgot that they were advisers, not administrators; that good and proper as their advice might be, there might be difficulties not apparent to them in at once pursuing it. A medical officer of health was not an autocrat; it was never intended that he should be one. Often and often it had happened that health officers, who had made this mistake, had sought his condolence with them in the tribulation they had thus brought on themselves. They all got from him pretty much the same advice, which was to be patient, to bear with the infirmities of their weaker and less intellectual brethren, and keep their own consciences clear amidst all discouragements by carrying out their duties to the best of their ability, and leave other people to look after their's."

Medical officers of health in possession should thoroughly grasp the truths in the above sentences, and pin them in their memories. The saying of poor RICHARD, "Mind your own business," pretty much comprises all that is contained in Dr. BALLARD'S advice, the medical officer has only to ascertain what his business is.

Annotations.

"Forsan et hæc olim meminisse juvabit."

MEETING OF THE BRITISH MEDICAL ASSOCIATION.

MAY we pronounce the Leeds meeting a success? If we accept the opinion of the profession in Leeds we may, but the profession in Leeds are interested witnesses, and are out of court. The number of visitors was not so large as we expected, and the absence of metropolitan men was notable. There were a few of the most eminent metropolitans, and some think that this meeting was none the worse for having so few metropolitans—that is an open question. Considering the work done by the organising committee, the arrange-

ments for the comfort of the visitors, the pleasure excursions, the meeting ought to have been a success. Private hospitality was most generous, and the public entertainments left nothing to be desired.

THE ANNUAL MUSEUM.

Unfortunately, the room devoted to the exhibits of drugs and surgical instruments was of a very limited size, and the general effect of the stalls was not so good as usual. The exhibitors were cramped, and could not display to such advantage their specimens. We understand that they were charged two or three shillings per foot for their stalls, a custom which we hope will not be established for the future. The exhibitors incur a very heavy expense in attending these meetings, and they should not be taxed in this way. The exhibits are highly instructive; we derive a certain advantage from seeing all the newest drugs, appliances, etc., and we hope that the firms who send their specimens also reap some profit. We should encourage the exhibitors. We believe that it would be highly advantageous to the association to have a permanent secretary to look after the museum and its arrangements; one who really understands the proper organisation of this kind of exhibition. Local secretaries are new to this kind of work; they have to learn their duties, and they have to sacrifice a certain amount of time and energy, and they have only one chance of showing what they can do in the way of organisation. This permanent secretary would take all the heavy work off the local secretaries (for we do not desire that the local officers should be abolished), and we believe that by any arrangement of this kind the museum might be very much improved. We publish in another column a detailed account of the museum.

DR. RENTOUL'S RESOLUTIONS.

The series of resolutions drawn up with such elaboration by Dr. Rentoul were withdrawn, and a single resolution was passed, referring the general question to the council of the association. A large number of members were interested in these resolutions, and much disappointment was felt at the absence of discussion. The atmosphere would have been cleared a little by free ventilation of views, but this is all that would have resulted from a discussion of the resolutions. If the council takes the question up with spirit, if the council will receive evidence, some good may result from the reference; but if the council be apathetic, or if the council wants to shelve the matter, the reference will be useless. We must hope for the best.

MR. EDMUND OWEN AND THE JOURNAL.

Mr. Edmund Owen had just grounds for bringing before the notice of the Council the editorial note which appeared in the *British Medical Journal*, seriously reflecting on him. The letter which drew forth the editorial thunder appeared in a subsequent issue, and we were very much astonished to find that Mr. Owen's letter was a very innocent one indeed, and certainly not deserving of the very harsh language used by the editor. The note reflected on Mr. Owen's character, and the apology tendered to him by the Council was fully deserved. The assessors of the journal, Dr. McAlister and Dr. Farquharson, are not to be congratulated on this episode, and if the supervision over the journal is to be of this nature, the couple of hundred a year will have been a very bad investment.

THE HOSPITAL QUESTION.

The Council have made a forward step. The profession at large will receive with favour the support given by the Council to the resolution, passed at the recent meeting, supporting the plea for a Royal Commission on the hospitals. If the British Medical Association is to prosper it must be in touch with the general practitioners; the Council appears to be alive to this fact. The journal has well supported the recent outcry against hospital abuse, and it has thus strengthened its hold upon the members. The signs of the times point to success on the part of the agitators for needed reform. It is through the Association we can best move.

SECRET POISONING.

Is secret poisoning common in Great Britain? Is it on the increase? These are startling questions, and we cannot here answer them offhand, because the evidence is only circumstantial and rests on suspicion. It is difficult to bring home guilt to the poisoner; we may suspect secret poisoning; we may, by showing our suspicions, stop the use of the poison; but our tongues are tied, because without the strongest evidence we cannot utter the thoughts we may have. A moral certainty is different from scientific certainty. The law as to certificates of death is very extraordinary. We are compelled to give certificates of death—if we refuse we are censured, or threatened with a lawsuit. We may have suspicions as to foul play. Sometimes the position is a painful one. What our duty is each one's conscience will dictate.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

The attack made upon the journal was not a very vigorous one. The letter sent to the Council required a dignified but crushing reply. The honour of the Association is in the hands of representatives of the profession, to whom the profession is as dear as it is to the signatories of the letter. The resolution, passed on the motion of Mr. Lawson Tait, and seconded by Dr. Barnes, should settle the question. The force of the opposition was weakened by the suspicion there was that the attack on the journal had a commercial origin; in other words, that it was prompted by a rival organ which once had a large circulation. If that journal approves of signed articles and signed reviews, why does it not adopt the system?

THE PREVENTION OF RABIES.

The following order has been issued from the office of the Privy Council. These who have followed the articles which have appeared in the Provincial Medical Journal will recognise the similarity, in the order issued, to the recommendations we have urged in season and out of season.

Agricultural Department,
Privy Council Office,

44, Parliament-street, Westminister, S.W., July, 1889.

Sir,—I am directed by the Lords of the Committee of Council for Agriculture to request that you will have the goodness to inform your Local Authority that the Privy Council are advised that in making regulations directing the muzzling of dogs on account of rabies, although it may be desirable that exception should be made in favour of packs of hounds, harriers, or beagles, or greyhounds or other sporting dogs, while being used for sporting purposes, or to any other dogs while being used for the capture or destruction of vermin, and in charge of competent persons, there does not appear to be sufficient reason for extending this exception to drovers' dogs or to dogs used for driving animals, such dogs being most dangerous to other animals, if they become "rabid," besides being able to perform their work without biting.

I am further directed to request that you will point out to the Local Authority the insecurity afforded by any alternative regulation which permits a leading strap or chain to be substituted for the muzzle, it being clear that a led dog (if he is unmuzzled) is able to bite any person or animal that may happen to pass within his reach; and this objection even more strongly applies to an alternative regulation which permits dogs to be in a public place under what is called control.

It would appear therefore advisable in applying regulations to any particular district to insist on the muzzling of all dogs (other than dogs while being used for sporting purposes or for the destruction of vermin as before mentioned) whilst being in any public place, whether the dogs are led or not, with a muzzle so constructed as to render it impossible for the dog while wearing the same to bite any person or animal.

The Lords of the Committee are of opinion that it would be useful if, at the foot of handbills announcing regulations, the following short description of the most marked symptoms of rabies in dogs were given:—

"Change of habits, restlessness, moving from place to place, often hiding in dark secluded corners, depraved appetite, gnawing and eating indigestible substances, altered voice, difficulty of swallowing but showing no dread of water, thick viscid saliva hanging from the corners of the mouth which the dog tries to remove with its paws, frequently snapping at the air or imaginary objects. These symptoms in the furious form of the disease are followed by paroxysms of excitement, in which there is an irresistible tendency to bite and attack other animals, especially dogs: the animal then wanders from its home, biting and snapping at every animal that may come in its way, emaciation and exhaustion rapidly follow with loss of nervous power, partial paralysis often supervenes and the animal drops and dies if it has not previously been destroyed.

"In the dumb or torpid form of the disease the premonitory symptoms are followed by dropping or paralysis of the lower jaw, rendering the animal unable to bite or bark, the tongue swollen and livid hangs out of the mouth, the dog in this condition seldom leaves its home but endeavours to remain quiet in some dark place, takes little or no notice of what goes on around it, paralysis of the hind limbs soon set in, and death quickly follows."

I am, sir, your obedient servant,

C. L. Peel.

INFANTILE INSURANCE.

The report of the Select Committee on Friendly Societies has just been issued. The Committee state that the public sympathy and indignation having been aroused by recent cases which have come to light, in which the money insured for, on the death of infants, appears to have acted as an incentive to neglect and even to murder of children, the committee directed their inquiries with special care to this branch of the subject. Several witnesses, including two coroners, expressed a strong belief not only that infant insurance is an incentive to crime, but that a widespread system exists, under which much neglect, cruelty, and crime takes place with impunity. From the nature of the cases it is almost impossible to obtain direct and inculpating evidence of criminality of this character, which is chiefly committed by a single individual in the privacy of home. The Committee believe that sufficient precautions are wanting to prevent larger sums than those authorised by the Act being insured for and paid on a child's death. The Committee add that many statistics have been submitted to them on the subject of infantile insurance, but they are not disposed to base any recommendations upon them one way or the other, owing to the difficulty of drawing therefrom a safe conclusion as to the general value of the system of assurance by companies and societies depending upon paid collectors. The Committee proceed to say that it must be regarded as a means, for which at present there is no effective substitute, of inducing very large numbers of the working classes to make some provision for burial, or for benefit to survivors at death, who would otherwise make none; and so far these societies and companies could not but be regarded, when well managed, as commendable institutions, always subject to the consideration that owing to the commission charged by collectors from 20 to 25 per cent., added to the ordinary cost of management—it oftens happens that nearly half the premium income never goes to the benefit fund. It had been shown that the cost of management of the industrial assurance companies has averaged 45½ per cent. in the ten years from 1877 to 1887. It followed, therefore, that for every shilling of benefit

assured for, the assurers have to pay nearly two-shillings. Among various recommendations as to the future management of industrial insurance companies and societies, to be embodied in the Act of Parliament, the Committee recommend that the Registrar of Friendly Societies chief office shall be constituted and termed "The Central Office," which shall have certain control over the management of the organisations; that it shall not hereafter be lawful to assure any child under ten years of age in more than one society or company; that it shall not be lawful for any society to which the proposed Bill shall apply to use the term "Friendly Society" unless prefixed by the word "collecting;" that no person under sixteen years of age shall become a member of a collecting society, and that all societies shall be registered. All companies shall be required to separate their industrial business from their ordinary business, and make annual returns in respect of such industrial assurance business. With regard to infantile and juvenile insurance, the Committee recommend that the age for the insurance of juveniles be raised from ten to sixteen. With reference to serious complaints as to the position and management of companies or societies, the Committee hold that when such a state of things as was disclosed by the valuation of a particular society in 1875—namely, a deficiency of £52,220—comes to his knowledge, it is the plain duty of the Chief Registrar, under Section 10, to publish information, either generally or in the particular districts. Looking to the importance attached in the public view to the fact that a society is registered, and to the confidence which is reposed on the action of the Chief Registrar, the Committee are of opinion that it is necessary that in future the provisions of Section 10 of the Friendly Societies Act, 1875, shall be more vigorously administered.

THE PHILOSOPHER'S STONE, OR WHAT?

The July number of the Provincial Medical Journal is out of print; it contained an article on Dr. Brown-Sequard's scientific experiments. Several correspondents have written asking for details. We may at once say that we regard all this kind of pseudo-scientific work as utterly out of the range of scientific medicine, and just as rational as it would be to eat a lion's heart to produce strength; though even that idea is not a new one, as at one time (let us say the Middle Ages, about which people know so little) the heart of animals was eaten in order to infuse courage. Old age will come; it is attended by certain symptoms, amongst which sexual impotence is only one characteristic. Its advent cannot be prevented, though it may be made more gentle by proper methods of living, by diet, hygiene, and the rest. We cannot give back youth; the fleeting years roll on, and then comes pale death, which knocks equally at the palace and the hovel, as Horace so beautifully tells us. But another higher authority has told us "that the age of a man is three score years and ten, and after that is sorrow and tribulation." How true an observer have we here; ask the septuagenarian, and he will answer, yes. Brown-Sequard, distinguished physiologist and professor at one of the French colleges, is now a septuagenarian, and the troubles of declining life have come upon him. He has tried to stave them off, succeeding, he tells us, by injecting into his body, sixteen times, a solution made from the testicles of animals. He has taken the testicles, pounded them into a pulp, adding a little water, so as to make a solution—as yet the price of these appendages of the male animal has not gone up. Brown-Sequard is anxious that ladies who have passed the meridian should be rejuvenesced by ovarian injections, and as a large number of women are ready for experiment, we await further developments. Contrary to our physiological teaching, Brown-Sequard has also preserved from decay a couple of patients, by teaching them masturbation, though not pushed to ejaculation, all of which is very wonderful and very scientific. But we live in an age of advance—even on these lines—and have to record many strange additions to medical knowledge. Phthisis has been treated by rectal injections of sulphuretted hydrogen. This plan had its votaries, and many instruments were sold, and many cases of cure reported by this ingenious and scientific method of killing the bacillus tuberculosis. The ingenious American who suggested the free use of beans made a good hit, and deservedly turned into ridicule this latest addition to science. We must leave Brown-Sequard to the mercies of time.

New Remedies.

Cocaine.—Dr. Squibb has lately pointed out a means of recognising the presence of isatropyl-cocaine in the cocaine of commerce, founded on a reaction first pointed out by Dr. Stockman, of Edinburgh University. When hydrochlorate of cocaine is heated with strong hydrochloric acid it splits up into its components without change of colour, but if isatropyl-cocaine is similarly treated it splits up into ecgonine, and a brown oily looking body, which is decomposed isatropic acid. This coloration also takes places when cocaine contains isatropyl-cocaine. As the latter is believed to be the constituent which sometimes gives rise to symptoms of poisoning, there is no reason why cocaine should not be obtained of such a degree of purity as to be used with confidence, especially since there is also a ready test known for detecting the presence of amorphous alkaloid—viz., in the acid reaction with litmus paper which the latter gives, and in the milky liquid which is formed when caustic ammonia is added to a solution of hydrochlorate of cocaine containing amorphous alkaloid.

Cola Nut.—Some carefully conducted experiments, made by Surgeon R. H. Firth, with the view of determining how far the claims made for these seeds are reliable, is published in the *Practitioner* for July. The author comes to the conclusion that cola is in no sense a food. Although it increases the total amount of urine, with a slight reduction of its total solids and a marked reduction of the extractives, it in no way affects the nitrogenous output of the body. It has a peculiar stimulant action on the nervous system, strengthening the heart-beat, and increasing the arterial tension. Taken continuously during times of exertion and fasting, it wards off to a certain extent the mental and physical depression peculiar to that condition. The infusion of the powdered seed with milk and sugar is an efficient substitute for tea and coffee, and superior to either for those affected with diarrhœa, owing to its astringent action. He considers that its alleged antagonistic action to alcoholic sequelæ is not proven. He finds that the cola nuts of commerce are not all genuine, some yielding no caffeine; and it is very necessary, therefore, to ascertain that neither the seeds of the bitter

cola (*Garcinia kola*), nor those of *Sterculia cordifolia*, neither of which contain caffein, are not present in any given sample. Chewing the nut continuously, and swallowing the saliva, he considers the best mode of using it during prolonged exertion.

Methacetin.—Some further information is now obtainable concerning this new antipyretic. It is related to antefebrin, which is acetanilide, phenacetin being oxyethyl-acetanilide, and methacetin oxymethyl-acetanilide. Its characters are given as follows. It crystallizes in shining white, odourless, and almost tasteless scales, melting at 127°C., and boiling undecomposed above that temperature. It is soluble in 526 parts of water, at 15° and in 12 parts at 100°, whilst phenacetin requires 2,500 parts of water at 15° and 86 parts at 100°, so that it is five times more soluble than phenacetin. It is freely soluble in alcohol and acetone, and in chloroform when warmed, but is soluble with difficulty in ether. It is also freely soluble in glycerine and fixed oils, especially when warmed, but less so in turpentine and essential oils. The aqueous solution is neutral, and is not altered by chloride of barium, silver solution, or ammonium sulphide. It should not leave any residue when heated on platinum foil. From phenacetin it is distinguished by its physical properties. If heated with insufficient water to dissolve it, it melts and solidifies again on cooling, but phenacetin heated with the same quantity of water does not melt.

Hydracetin.—The use of this chemical in psoriasis appears to require a certain amount of caution. The ointment recommended by Dr. Guttman for psoriasis contains ten per cent. of it; but Dr. Oestricher, who used a twenty per cent. lanolin ointment of it, found that, although he obtained good results so far as the action of the drug on the disease was concerned, yet, after using the ointment about seven times, severe symptoms of poisoning were produced, the patient complaining of increasing exhaustion and weakness of the limbs, and a feeling as if a serious illness were impending. The urine had a mahogany colour, with a greenish tinge.

Antipyrin.—Attention has recently been directed to the advisability of prescribing complex new remedies in as simple formulæ as possible, such as distilled water and a simple flavouring agent, on account of the inconvenience arising from the unexpected changes or decompositions that may take place. Thus it was found, by M. Ollivier, that antipyrin added to fluid extract of cinchona precipitates all the active principles together. The precipitate is, however, soluble readily in weak acid, and may therefore be soluble in the gastric juice. Again, it has been observed by M. Blainville that four parts of antipyrin with five of chloral hydrate and fifteen of water give an oleaginous (liquid at first milky) which is deposited from the water, and soon crystallizes, and then no longer possesses the taste of either, but has a flavour like that of coriander.

Naphthol-Camphor.—It has been found by M. Desesquelle that if 200 parts of camphor are heated with 100 parts of β-naphthol a liquid is formed, miscible with fixed and volatile oils, and with ether and alcohol, but insoluble in water. The application of the mixture of the two substances is not attended with pain, owing to the anæsthetic action of the camphor. The liquid is also capable of dissolving cocaine hydrochlorate and the cinchona alkaloids in considerable proportion, and ninety parts will dissolve ten of iodine. The mixture also, of naphthol and camphor, does not attack surgical instruments.

Rubidium Ammonium Bromide has been found by Professor Laufenauer to act in some cases more favourably than potassium bromide. He administered it to twenty-two patients, seventeen of whom were epileptic. The quantity given amounted on the average to six grains daily. In doses of four or five grains given in the evening it acted well as a sedative and hypnotic.

Periscope.

I.—GLEANINGS IN MEDICINE.

By W. B. KESTEVEN, M.D.

A Case of Glioma of the Retina. By Dr. Rolland, of Toulouse (*Le Progrès Médical*, July 20th, 1889).—Glioma, the only neoplasm that is developed in the retina, is also a rare affection. Dr. Rolland could only collect sixty instances in the literature of all countries that he could consult. It is met with only in children under twelve years of age, and principally in infants from two months to four years. Boys are the subject thereof more frequently than girls in the proportion of sixty per cent. It is fatal to all infants that it attacks. It is at first a purely local disease; gradually the cells encroach upon the choroid and the optic nerve and creep into the cranial cavity, and later still the gliomatous cells are found in the lymphatic glands, the liver, the kidneys, and the bones. The cure, without relapse, after many years, is possible where extirpation of the globe has been performed early. The fate of the patient depends upon early extirpation, while the disease is in its local stage. The diagnosis, is the more difficult in as much as the glioma, does not give any very marked indication of its advent. The patient may be in excellent health, and the first symptom will be (1) that peculiar reflection of the retina known as "Beer's amaurotic cat's eye; (2) the accidental discovery of monocular blindness; (3) inflammation of the outer structures; (4) strabismus; (5) dilatation of the pupil; (6) hemeralopia; (7) discolouration of the iris; (8) nystagmus. The examination by opthalmoscope will reveal a circumscribed tumefaction on the retina of a yellowish-white colour, furrowed by vessels very different from the normal retinal vessels.

On the 6th April, 1889, the patient was presented for consultation. The infant was of the male sex, emaciated and strumous. The right eye was seen to be double the size of its fellow; hard to the touch, and fixed in the orbit, causing protrusion of the lids; the cornea flat, dull, and semi-opaque at its centre. The iris seemed to be moulded on the concavity; the pupil was indistinguishable. The sclerotic was slate-coloured and tuberculated. The ophthalmoscopic examination of the left eye showed nothing abnormal. The parents enjoyed good health, and had four other children free from any defect of vision. The child's health up to that time had been good. On several occasions the retina had presented the peculiar glistening appearance, described by Beer as "cat's eye." The globe continued to enlarge, and the patient suffered so intensely that enucleation was indispensable, and four days after the operation the child was removed to its home. Dr. Rolland does not claim for the case a perfect cure, but immediate relief to intense suffering, and awaits anxiously the possible occurrence of the return of disease.

The Treatment of Tetanus by Pilocarpine (*L'Union Médicale*, July 6th, 1889).—Dr. Casate reports the successful treatment of three cases of tetanus by injection of hydrochlorate of pilocarpine, but does not state the dose used. In similar cases, however, recourse may be had with success to doses which might be fatal to men and animals in health.

The Multifarious Employment of Peroxide of Hydrogen (*Der Fortschritt*, Genf. June 20th, 1889).—This substance is a powerful bleaching agent, and as such is much used in arts and manufactures. As a disinfectant it possesses predominant properties. It destroys bacteria, like ozone, without exerting any poisonous effects upon the structure in which its influence is exerted, and is therefore employed for the disinfection of wounds, the atmosphere of sick chambers, and for general household cleaning. Peroxide of hydrogen is also serviceable as a preservation against fermentation.

Pathology and Cure of Snake Bite. By A. Mueller, M.D., Yackandanah, Victoria (*The Australasian Medical Gazette*, May, 1889).—A young man bitten by a "tiger snake" walked eight miles after the bite had been cut out; ammonia was then injected, but the poison had taken such effect that the case appeared hopeless. However, strychnine and cocaine were injected, and the patient kept walking about until he was out of danger. Fifteen minims of liq. strychninæ, and one grain of cocaine were injected. Strychnine dispels snake bite coma, besides restoring the power of voluntary muscular action, since its effects are not confined to the anterior columns, but extend over all the motor centres. Strychnine, the author affirms to be an unfailing antidote, while here is a strict correspondence between the quantity required and the amount of snake bite poison absorbed. Cases may occur in which the quantity required may amount to a poisonous dose; in cobra bite possibly a grain or more; whilst in Australia seldom above half a grain is required. In urgent cases one sixth, in milder cases one twelfth, of a grain may be injected every half hour with perfect safety. A glass or two of wine, or spirit and water will show by their exhilirating effects that all danger is past. [Statistical results of this treatment are desirable.—Rep.]

A new Orthopædic Operation. By Dr. Defontaine, Paris (*Annales d'Orthopédie*, July 1st, 1889).—Dr. Defontaine describes at considerable length the steps of an operation he has in two cases performed to fix at a right angle the foot in cases of infantile paralysis, of which the following is a short abstract:—In one of these cases, paralysis of the motor-muscles, dated more than ten years; the others upwards of two and a half years. The steps of the operations briefly related, are the opening of the tibio tarsal articulation on the external aspect by two perpendicular incisions, one anterio-posterior passing by the lower border

of the external malleolus to the posterior extremity of the meta-tarsus; the other passing vertically in front of the external malleolus, exposing the fibia-peroneal articulation. The astragaloid ligaments are divided, and if necessary the pereonal tendons also are divided. The articular surfaces were abraded by an osteotome. The arteries were tied with fine catgut, and the foot enveloped in salicylic wadding, and placed at a right angle.

On the Therapeutic Action of Senna Pods. By A. W. Macfarlane, M.D., Glasgow (*Lancet*, July 27th, 1889).—"The products of the senna plant, as imported into this country," Dr. Macfarlane points out, "consist of leaves, stalks, pods, and flowers, with certain other extraneous materials; these are sent to the great prisons to be picked, and the leaves are selected and returned to the druggists, while the other parts are rejected." The properties of the pods differ from those of the leaves. The infusion of the pods is free from taste and smell, "certainly it is devoid of the characteristic odour and flavour of senna." It appears to increase activity in the muscular movements of the whole alimentary canal, acting quite as much on the colon and rectum as on the small intestines. It is slower in its action than an infusion of the leaves, but equally certain; an ordinary dose produces without fail one motion, seldom more, of soft consistence, in from eight to ten hours, and without exciting any congestion of the pelvic vessels, or increasing or aggravating hæmorrhoidal or menstrual discharges. It is, in short, a reliable evacuant, free from irritating properties, such as cause griping and flatulence. The dose for an adult is from six to twelve pods; for the young and aged, from three to six; or liquid extract, dose ℥ss. to ℥j.; prepared by Rankin and Borland, Kilmarnock.

On the Treatment of Chorea by Prolonged Sleep. By Dr. Bastian (*Laneet*, July 13th, 1889).—This treatment, Dr. Bastian states, has been based upon a very definite principle. It is known that almost invariably the movements of chorea are arrested by sleep. "The disordered actions of the nervous centres upon which these movements depend are therefore also arrested. By greatly prolonging this period of rest we may accomplish two things: first, we may cut short the mischief which is almost inevitably being done to nerve centres, by the maintenance of this incessant and unnatural activity; and secondly, during such periods of prolonged rest we afford an opportunity for the gradual abatement of the functional perversion in certain parts of the nervous system (wherever situated) which has been the primary cause of the malady. Such a restoration of the normal equilibrium of functions, under the influence, as our forefathers would say, of the *vismedicatrix naturæ*, is the main object of this method of treatment." Dr. Bastian relates in full the details of a severe case of chorea treated upon this principle, and further states that he has treated, in the last twelve years, some eight or nine cases in this manner. "Some of the cases have been notably improved; other very chronic cases, however, have not derived much permanent benefit. In none of the cases has any evil resulted from the treatment." In the case related the patient was kept asleep (more or less) for three weeks, although two weeks had been the previous limit. Dr. Bastian gives an outline of the kind of cases for which he considers this treatment suitable—in ordinary cases of chorea he does not have recourse to it. The worst and most protracted cases can be treated on this principle only in the wards of a hospital, or under the care of special nurses in private practice. [For a more complete account of this mode of treatment, we would desire to refer our readers to the pages of the *Lancet*.]

The Treatment of Pulmonary Tuberculosis by Intra-Pulmonary Injections of Camphorated Naphthol. By M. Fernet (*Gazette Hebdomadaire des Sciences Medicale*, July 21st, 1889).—Dr. Fernet has injected the camphorated naphthol forty-one times in four patients in the second stage of disease, characterised by moist crepitation. In one case a small cavity was detected. Three injections were made once or twice a week with a Pravas' syringe furnished with a needle longer than usual. At each injection Dr. Fernet injected 0.15 centigramme of camphorated naphthol—0.05 centigramme of naphthol. These injections were made in the first or second intercostal space, equidistant between the border of the sternum and the edge of the axilla. In twenty-two out of the forty-one injections nothing untoward occurred; in several of the other cases a pain was experienced down the course of the nerves of the arm; in some a troublesome cough, produced, Dr. Fernet supposes, by the penetration of the vapour of camphor to the bronchial tubes. In a few instances slight hæmoptysis occurred. As far as the results are concerned in the four patients—three were notably improved; in the fourth the disease had made progress while in the hospital. In all. the expectoration was much diminished, and the crepitant râles had nearly disappeared.

The Treatment of Epilepsy by "points de feu répétées" on the Hairy Scalp (*L'Union Médicale*, July 6th, 1889).—M. Féré confirms this treatment, which, he states, he has employed the last two years. Two patients have been considerably relieved, if not cured, in that time. One of these experienced twenty-one fits in 1886, seven in 1887, only one in 1888, and none during the present year. The other had sixty-three attacks in 1886, forty-five in 1887, and five in 1888. [The details of the *modus operandi* are not given.]

Subcutaneous Mercurial Injections (*Gazette Hebdomadaire des Sciences Médicales*, June 30th).—M. Lesser dwells upon the disadvantages of these subcutaneous injections, especially of the insoluble preparations. With these a deposit of mercury may take place, which will afford a centre whence it may permeate the system, and give rise to severe mercurial poisoning. Fatal cases of kind were related at the Congress at Breslau. The indications for the injection of the soluble salts have reference to the urgency of the requirement of the medicine.

On the Importance of Gonococci in Diagnosis of Blenorrhagia (*Gazette Hebdomadaires des Sciences Médicales*, June 30th).—M. Neisser, of Breslau, submitted the following propositions at the Dermatological Congress at Prague:—1. The gonococcus is the morbid agent in the disease. It is always to be found in contagious blenorrhagia. It may be associated with other microbes, but the infectious character determines its specific nature. 2. The number of the gonococci will not always be in exact relation with the suppuration. This being a reaction of the mucous membrane against the gonococci, the reaction will be less in degree with second or third infection. 3. The presence of the gonococci is of importance for the establishment of the diagnosis, in a medico-legal, or hygienic point of view.

The Apostoli Treatment of Uterine Disease (*Centralblatt fur Gynäkologie*, 22nd June, 1889).—The principal point in this treatment is the use of the electric current obtained by the employment of a large external electrode, covering the greater part of the abdominal surface, so that the electricity is distributed extensively. An internal electrode ends in a platinum sound, and is introduced within the uterus. In some myomata this pole may consist of an acupuncture needle which may be passed into the tissues, to the depth of ½ to 1 c.m. The sound and needle are protected by antiseptics. The battery employed is Gaiffe's, with Leclanchè elements. This treatment it is urged is safe, simple, and easily carried out.

The Treatment of Hyperpyrexial Sunstroke by the Cold Bath. By H. F. Forbes, M.B., Brisbane (*The Australasian Medical Gazette*, May, 1889). — Dr. Forbes gives the notes of four cases of severe sunstroke with the treatment by cold bath. The pathology of this affection is now Dr. Forbes observes established to be pulmonary, and its characteristic symptoms due to paralysis of the brain centres by the overheated blood. "Hyperpyrexial sunstroke," Dr. Forbes remarks, "is simply a paralysis of the heat regulating mechanism with consequent paralysis of the vaso-motor and respiratory centres. If this paralysis is sudden, coma occurs at once; if gradual, three well-marked groups of symptoms appear in order, viz., restlessness with confusion of thought, delirium with epileptiform convulsions, and finally coma. These symptoms being due to high temperature, the principal of successful treatment must be the abstraction of heat and the rousing into action of the paralysed brain centres." This is to be accomplished by the ice bath, at 65° or lower, if ice is plentiful, at the same time that the patient is in the bath, ice-water is to be poured on his head, from a height of four or five feet. Relapses should be anticipated by the cold bath as soon as the patient becomes delirious, with a rising temperature. The result of this treatment in the hands of Dr. Forbes, has been encouraging. "To be successful, however, it must not be withheld on account of thready pulse, gasping respiration, and cold skin, but must be used quickly and boldly in face of such apparent contra indications. The cold bath instead of inducing greater collapse, acts as a very powerful and unique stimulant."

II.—SELECTIONS FROM FOREIGN MEDICAL JOURNALS.

By G. F. CADOGAN-MASTERMAN, M.D.

Glioma of the Retina. By Dr. E. Rolland, Toulouse (*Le Progrès Médical*).—Glioma, the only neoplasm capable of development in the retina, is, happily, a very rare disease. In searching through an extensive series of observations made by ophthalmic surgeons of all countries I have found but sixty cases recorded. They are enough, however, to establish the following propositions: Glioma of the retina is only seen amongst children under twelve years of age, and principally amongst those between two months and four years. Boys are attacked more frequently than girls, in the proportion of sixty-one per cent. The disease, if left to itself, is fatal in every case it invades, but at its commencement the mischief is purely local. The minute cells of the new growth gradually invade the choroid, the optic nerve, the whole

contents of the orbit, and then the brain itself. Later it may appear in the lymphatic glands, the liver, the kidneys, and the bones. A cure, after extirpation, has remained perfect for a period, in one of five and another of twenty years, without relapse, but the operation was performed very early. Should a relapse occur it is better to abstain from any further operative interference, as it would be wrong to operate at all if there be any indication that the disease has extended beyond the eye originally attacked. These considerations are full of interest not only to ophthalmic surgeons, but to every medical man engaged in general practice; to the latter, perhaps, most so, for it depends upon their acuteness of observation and diagnostic skill to detect the disease early enough for operation to be of any use; for it is not a mere question of impairment or loss of sight, but loss of the life of the little patient if the disease shall have been overlooked in the only stage when the surgeon can successfully intervene. And if the operation of enucleation be advised and accepted when the growth is purely local, it is the family medical attendant, not the oculist, who has the happiness of saving the patient's life.

But, it must be confessed, to recognize the disease in this early stage is very difficult, and its differentiation is more difficult still. The first *crux* is that it appears when the child is otherwise in perfect health. There is good appetite; natural, sound sleep; a clear complexion, and all the boisterous gaiety of untrammelled boyhood; and the eye is neither inflamed nor painful. But, then, we have a characteristic reflection from the fundus of the organ exactly resembling that which we all have noticed occasionally in the eye of the cat, and which was first pointed out, and called by Beer, "the amaurotic cat eye." The discovery that one of the apparently-healthy eyes is sightless. Later, surface inflammation, strabismus, unequal dilatation of the pupils, discoloration of the iris, nystagmus, hemeralopia. The first is pathognomonic; the others are of value only because they may and ought to lead to the ophthalmoscopic examination of the eyes. When this is done a circumscribed projection of the retina is seen, of a yellowish white, or brilliantly white, crossed by numerous tortuous vessels, having a very different arrangement to the normal retinal arteries and veins. Its surface is usually uneven, not as if bounded by some covering membrane, but irregularly embossed. Some of the vessels are seen to be running on its surface, others penetrating it at various depths.

It must not be imagined, however, that the diagnosis is even approximately certain. M. Poncet (of Cluny) says that he has examined at least half a dozen eyes which have been sent to him as examples of glioma, and found them—when too late—quite free from the disease. An irido-choröitis, with detachment of the retina, having given rise to the mistake; and Critchett and Bowman report (*Lancet*, May, 1854,) a case in which an enucleated eye was found to have the yellow tint due to an inflammatory exudation at the back of the crystalline lens; and M. Vassaux, an oculist of Amiens, extirpated the eye of a child two months old, which was mydriatic, with a dull yellow tint in the pupil and synechiatic, and in which the ophthalmoscope seemed to shew a fixed tumour, with a wrinkled surface covered with dilated vessels, which he pronounced to be "glioma," but which turned out to be a fibro-plastic growth from a terminal loop of the hyaloid artery covered with a delicate epithelial envelope. Desmares removed another eye in which a partial detachment of the retina led to the same error. But, after all, these mistakes as far as the patient is concerned, are not to be regretted; in each there would have been partial loss of sight, and an artificial eye is far preferable to a globe rendered opaque by disease. It is much better that the mistake in diagnosis should have been made than that the operation should not have been performed, for an eye with a detached retina is so extremely apt to set up sympathetic inflammation in the other, with the result of complete blindness, that the error is a fortunate one; and, in face of the fact that an unremoved glioma is *always* fatal, it is well to keep in mind that the autopsy of even a healthy eye is preferable to the *post-mortem* of a cancerous patient.

On the 6th April, 1889, a little boy, three years and a half old, was brought to me in the most piteous state imaginable—wasted, strumous, his face distorted with suffering and incessantly crying, screaming with pain. "Ah! Monsieur," said his mother as she vainly tried to silence him, "if you cannot save my child, at least spare him this martyrdom and me the agony of witnessing it!" On removing the bandage the right eye was seen to be swollen to double its proper size, hard, immovable, and almost bursting through the œdematous eyelids. The cornea was flat and opaque, no pupil to be seen, and, of course, any examination of the interior of the eye impossible. It was clearly a case of malignant disease, and the microscope showed it subsequently to be an unusually large-celled glioma.

The history of the case is: that on the 2nd of January, 1887, several persons noticed in the evening the extraordinary brilliancy of the child's right eye; the next morning, however, in full daylight nothing of the kind was to be seen, it was only at night when the lamp was burning that this singular brightness was visible—due, of course, to the then dilated pupil. Four months afterwards the child, still enjoying apparently the most perfect health, was sitting one evening under the table with the cat beside him, and the mother remarked with some emotion, that the eye and those of the animal had the same uncanny appearance. This went on for twelve months without any medical opinion being taken. In May, 1888, it was evident that the eye had increased in volume, that the pupil was always dilated and had become cloudy; but the child was as well as ever. By the middle of August, however, the increased size of the eye alarmed the parents, and they consulted a local medical man who assured them that the sight of the eye was lost, but does not seem to have realised the gravity of the case. Shortly afterwards pain commenced, and the poor child was always wailing, "*Maman, maman, l'œil me fait trop de mal, je ne puis plus y tenir.*" Still nothing was done, and in February, 1889, the swelling gradually subsided, and the parents were urged by the usual village wiseacre *not* to trust the child to a surgeon for he would be sure to want to take the eye out! By the next May, the sufferer had completely broken down; his cries were continuous, he could not sleep, appetite failed, and he had wasted to skin and bones, and at last, when the parents were convinced that nothing could save him, the oculist was asked to do it! Enucleation was performed the next day under chloroform, care being taken to divide the optic nerve as far back as possible, and to clear out the whole contents of the orbit to the periosteum. There was free hæmorrhage, checked by stuffing the cavity with strips of lint soaked in a cold solution of boracic acid. The operation was finished at 10 a.m., and at 5 p.m., when, seen again, all was going on well, all oozing of blood had ceased, and the child, to the great delight of his parents, had asked for some soup and had eagerly taken it. He slept well all night, and convalescence was rapid and uninterrupted. The disease may return, but the child is for the present, at least, relieved from all pain and discomfort.

A word as to the time for introducing an artificial eye: as a rule, I direct one to be fitted eight days after the operation; but in this case, where it is so important to avoid any and the slightest form of irritation, I have directed the parents to wait for at least a year.

III.—NOTES FROM FRENCH JOURNALS.

By H. R. HATHERLY, M.R.C.S.

Hypnotism (*Gazette Hebdomadaire des Sciences Medicales de Bordeaux*).—M. Tillaux has operated on a patient for cystocele during hypnotic sleep. The patient, who was a hysterical subject, entered the operating theatre during her sleep, and felt nothing of the operation. It was suggested to her immediately after the operation that she should pass a good day, and she suffered no pain. Unfortunately it was not suggested that there should be no bleeding, and this complication had to be remedied by tampons. This degree of insensibility cannot be induced in all hypnotic subjects.

Instructions to Prevent Tuberculosis (*Ibid*).—M. Villemin has prepared a series of instructions for public use to prevent tuberculosis, which disease, he asserts, is parasitic, virulent, contagious, and transmissible by a microbe. It is the recognition of its contagious character which must guide the public in the precautions to be taken against this disease, which may penetrate the organism in a variety of ways. There is a condition of the general health which predisposes to infection, and some persons are peculiarly susceptible. Either milk or uncooked meat may convey the pathogenic germ to the digestive canal. M. Villemin intends to submit to the academy for discussion the following instructions:—(1) Expectoration by phthisical people, being the most formidable agent in the transmission of tuberculosis, there is public danger in spitting on the ground, on carpets, coverings, curtains, napkins, handkerchiefs, and sheets. (2) The use of spittoons should be enforced everywhere and on everybody. Spittoons should always be emptied into a fire, and cleansed with boiling water; they should never be emptied on dunghills or in gardens where they may convey tuberculosis to fowls. They should not be emptied in closets. (3) No one should sleep with a tuberculous patient, and the room should be inhabited as little as possible; young children especially should not sleep in the room. (4) The places inhabited by phthisical people or by those considered to be predisposed to contract tuberculosis should be separate; also for patients born of phthisical parents, or who have had measles, small-pox, pneumonia, repeated attacks of bronchitis, or attacks of diabetes. (5) Objects which may have become contaminated by a phthisical patient (linen, clothes, furniture, play toys, etc.) should only be used after disinfection by stoving or other means. (6) It should be compulsory that rooms in hotels, furnished apartments, chalets, or villas in watering places, or winter stations, should be furnished in such a manner that disinfection can be readily and effectively carried out

after the departure of each patient. It would be best for the chambers to be without curtains or bed-hangings, to be lime-washed, and that the floor should be covered with linoleum. The public is chiefly interested in preferring those hotels where hygienic precautions are taken, and means of disinfection are provided.

Tinea Favosa in a Child Six Weeks Old (*Journal de Medicine de Paris*).—M. Augier records a case of this disease which is rarely met with in the early months of infancy. In the case in question the crusts of favus were not on the hairy scalp but on the temporal region, where there was, all the same, a fairly distinct down. Schœnlein's Achorion was discovered by microscopical examination. Looking at the case from an etiological point of view, the infant had a sister whose scalp was covered with favus, and as this child was in the habit of taking care of the baby, and holding it in her arms, there can be little doubt about the source of contagion.

Treatment of Mental Diseases by Hyoscine (*Journal de Medicine de Paris*).—At a meeting of the Society of Biology Dr. Magnan claims that hyoscine produces remarkable effects in acute mania. A few minutes after the subcutaneous injection of hyoscine all the morbid symptoms diminish. At first the patient experiences a faintness and some disorder of accommodation, with dilatation of the pupils, followed shortly by drowsiness and quietude lasting from five to ten hours. Once only he noticed an unfavourable symptom: it was in the case of a phthisical maniac, who, after injection of hyoscine, had a marked tendency to syncope, which, however, was of short duration. Hyoscine has been employed by Dr. Magnan in other forms of mental disease, but the cases are too few to permit any generalisation. In one case, a young hysterical patient, who had profuse localised sweatings of the hands, was relieved for many hours after the subcutaneous injection of a half-milligramme of hyoscine. No remedy for mania has proved so serviceable in the hands of Dr. Magnan as hyoscine.

Sulpholeinic Acid as a Solvent in Pharmacy (*Journal de Medicine de Paris*).—This acid, sometimes called the universal solvent, and obtained by the action of sulphuric acid on vegetable oils (the chemical process is very complicated), which is rendered neutral by repeated washings in a solution of chloride of sodium and ether. When concentrated it forms a yellow liquid, oily, viscid, of neutral reaction, having at first a sweet taste which becomes shortly bitter and astringent; its specific gravity is 1.023. It is soluble in all proportions of alcohol, and mixes with one or two parts of water without losing its oily character. Dissolved in a large quantity of water it forms a clear liquid, slightly opalescent, frothy, and remarkable for its great affinity for water, even when boiled for some time. At a temperature below freezing point it forms a yellow mass resembling vaseline. It combines with a variety of substances, which then become completely soluble in water, or else form emulsions with it; for instance: ether, chloroform, turpentine, bisulphide of carbon, oil of mustard, and other essential oils. Warmed or boiled it dissolves a great number of organic and inorganic substances such as sulphur (two per cent.), iodoform (three per cent.), camphor (twenty-five per cent.), naphthalin, chrysophanic acid, several colouring agents, etc. These solutions penetrate the skin rapidly and energetically, and are speedily and completely absorbed by it. It may be seen, therefore, that sulpholeinic acid possesses many important advantages; it is superior to vaseline, oleic acid, glycerine, and other vehicles for remedies prescribed for external use.

Black Tongue (*Annales des Maladies du Larynx*).—Black tongue is an indolent affection situated at the back part of the tongue. It often passes unnoticed, or it is first perceived by the patient accidentally. It is caused by the production of long papillary filaments, having a uniform colour varying from a light to a black brown. These filaments are due to hypertrophy of the normal papillæ, recovered by dry and hard epithelial cells, and surrounded by abundant spores. Is it a trophic disorder, is it due to the irritation produced on the papillæ by a fungus? These questions have yet to be solved. That which is known is, that black tongue frequently makes its appearence in the course of diabetes. The treatment consists in scraping the part affected, and the application of strongly alkaline solutions, which do not, however, prevent relapses.

Poisoning by Bismuth (*Gazette Hebdomadaire des Sciences Médicales*).—Experiments recently made with bismuth establish the fact that it possesses poisonous properties. Subcutaneous injections of the citrate of bismuth and ammonia are often toxic. Stomatitis often follows the injection of a centigramme of bismuth in a cubic centimetre of water. Amongst other symptoms of poisoning by bismuth, M. Balzer points out, diarrhœa, hœmatemesis, intestinal hæmorrhage, and dyspnœa, perhaps, in relation to blood changes. A dog suffered from a well-marked double opacity of cornea, similar to that which has been observed in poisoning by chloride of ethyl, evidently due in this case to deep seated lesions in the anterior chamber.

The Quality of Chloroform (*Ibid*).—Dr. Regnier is of opinion that it is not only difficult to procure good chloroform, but that it is still more difficult to preserve it. He has studied the question of chloroform anæsthesia with great care, and his conclusions are that chloroform should always be rectified the day before it is wanted. Deaths from chloroform in man and in animals are due to the use of an impure anæsthetic. It is not very convenient to rectify chloroform every time that it is required for an operation, and it is not every pharmaceutical chemist who is in a position to do it. Dr. Polaillon proposes the employment of a mixture of chloroform and alcohol suggested by Regnault, as, according to this chemist, the mixture insures the unalterability of the chloroform; at the same time it must be acknowledged that this mixture has not proved successful in the hands of some surgeons.

Injurious Effects of Listening to the Telephone (*L'Union Médicale*).—Dr. Gellé has observed in several persons ear troubles, which he attributes to abrupt and noisy sounds conveyed by the telephone, from the ears being too close, or from the degree of attention required by this particular mode of conveyance of sonorous impressions. Perhaps there may be a certain nervous predisposition in some cases, or some secondary pathological condition may pre-exist in the organ. In one case a man of great ability, whose occupation demands considerable intellectual effort, and also very frequent telephonic communication, suffered from a condition of nervous excitement and hyperæsthesia of the hearing apparatus; his condition was such that sound caused vertigo and bourdonnement, and he was liable to disquieting sensations of giddiness. In another case a young girl, who was employed for telephonic correspondence in a large establishment, was attacked with deafness and noises in the ears, also hyperæsthesia of the hearing apparatus. In both these cases the disorders ceased after the use of the telephone was discontinued. In some cases pain, deafness, tinnitus, and neuralgia, accompanied inflammatory conditions of the tympanum, which were probably due to the same cause.

Treatment of Erysipelas by Picric Acid (*Journal de Medicine de Paris*).—M. Calvelli recommends a very simple treatment of erysipelas. He mops the part affected five or six times a day, with a solution of picric acid in water (1.5 in 250). In addition he makes use of hypodermic injections of quinine, and he states that there is a diminution of inflammatory swelling, and of pain within from twelve to twenty-four hours. A passive œdema replaces the inflammatory swelling in very severe attacks, or in migratory forms. According to Calvelli the picric acid acts as a protective varnish, and modifies the peripheric circulation by exciting vaso-constriction.

Chronicles of Hydrophobia (*Journal de Medicine de Paris*).—The disciples of M. Pasteur continue to alarm the populace. If they are to be believed, every person who has been licked by a dog which is suspected, is liable to die of hydrophobia if he does not immediately apply to the Pasteur Institute, and at all cost help to swell the number of persons treated. Thus it is pretended that Mr. L——, who died of a nervous affection on the 17th of May, died of hydrophobia, *because he had been licked by a dog*. The same dog bit a child who was sent to the Pasteur Institute, and who is at present in good health. We reply to M. Pasteur's disciples:—

1. L—— did not die of hydrophobia, but of an ill-defined nervous affection which did not present a single characteristic of hydrophobia. This is the deliberate opinion of the doctor who treated the case.

2. The child which you pretend to have cured, and which was bitten in May, has not yet reached the limit of the period of incubation, and consequently it is not certain that it is yet protected.

3. It is understood how important it is for the antirabic Pasteurian therapeutics to establish a parallel between these two cases; one cared for at the Institute is well, the other not so cared for died. But it is proved by numerous witnesses, and especially by the doctor who treated the case, that L——, who had possibly been licked by a suspected dog, did not suffer from hydrophobia, and did not die of that disease.

Coronilla in Heart Disease (*Ibid*).—Cardot and Spillman have tried the effects of coronilla in heart disease; it acts more particularly on the cardiac muscle of which the contractility is increased. Dr. Spillmann has exhibited it principally during the asystolic stage of heart disease, and out of seventeen patients treated, in eight the remedy proved efficacious; in two there was slight improvement, and in seven cases no benefit was derived. The diuretic action of the drug was frequently shown, the quantity of urine passed being increased from 200 centimetres to four and even eight pints. Coronilla acts feebly on the frequency and rhythm of the pulsations, but it causes an increase in the volume of the pulse, an increased diuresis diminution of œdema, and relief of dyspnœa. The drug was administerd for three or four days in succession, and produced its therapeutic effects in from twenty-four to thirty-six hours after the first dose, but twenty-four hours after the last dose the patient relapsed into the same condition as before the administration of the remedy.

IV.—NOTES FROM RUSSIAN, POLISH, AND SWISS JOURNALS.

By VALERIUS IDELSON, M.D., BERNE.

On the Gastric Digestion in Pulmonary Phthisis and Emphysema.—In the Polish weekly *Gazeta Lekarska*, No. 20, 1889, p. 44, Dr. Adam Chelmonski (pron. Khelmonskee), house physician to Professor J. J. Stolnikoff's clinic, in Warsaw, published an able paper on the influence produced by chronic pulmonary disease on the gastric juice, and motor and absorptive powers of the stomach. In all, twenty-six patients were examined, of whom eleven were suffering from chronic pulmonary consumption, and fifteen from emphysema. The essential outcome of the author's researches may be given as follows :—

1. In cases of chronic phthisis with an apyretic course, very often, though not always (in eight out of eleven cases), no free hydrochloric acid can be detected in the patient's gastric juice, while the proportion of pepsine proves to be exceedingly small. The gastric motor power (tested by Leube's mechanical method) is frequently weakened, the gastric absorption invariably retarded to a considerable extent. [Iodine could be detected in the patient's saliva only twenty to twenty-five minutes after the internal administration of iodide of potassium on an empty stomach.]

2. Such failure of the gastric functions is dependant partly upon general anæmia and exhaustion, partly upon chronic fibroid endarteritis [which, according to Dr. N. S. Ippa's researches, represents a constant morbid change in phthisis, *vide* his *St. Petersburg Inaugural Dissertation*, 1889]; partly upon venous congestion of the stomach, and, contrary to Edinger's and Rosenthal's assertions, only in exceptional cases may be attributed to amyloid degeneration of the arteries of the gastric mucous membrane. [The corollaries are supported by the following facts derived from the registers of the Warsaw clinics for 1882-85 : Out of 162 necropsies in cases of phthisis, amyloid degeneration was found only in eight cases, the organs affected being kidneys (eight), spleen (six), and liver (two). Out of eighty-six cases, in forty-four the gastric mucous membrane was found anæmic, in thirty-two affected with chronic catarrh, in three with acute, in three gastric cancer was present, and in two ulcer.]

3. In emphysema, during attacks of asthma with bronchitis and œdema of the lung, the gastric juice invariably shows a total absence of a free hydrochloric acid, and a very considerable decrease in the proportion of pepsine. During free intervals, however, the juice seems to return to its normal condition.

4. The changes seem to depend upon venous congestion of the gastric mucous membrane, leading to catarrh. A certain causal significance may be also attributed to a weakened state of the diaphragm. [Out of thirty-six necropsies in cases emphysema, in twenty-one chronic catarrh of the stomach, in eleven anæmia, and in six cancer, were found. The liver proved to be in a "nutmeg" condition (*Hepar moschatum*) in thirty-one cases, fatty in two, cirrhotic in three, anæmic in two.]

Nephrectomy for Malignant Tumours of the Kidney.—Dr. Albert Siegrist, of Zurich, has collected (*Zurich Inaugural Dissertation*, 1889) from international literature sixty-four cases of malignant disease of the kidney, in sixty-one of which total nephrectomy, and in three only exploratory nephrotomy (in children) was performed. In 54 per cent. of the cases sarcoma, and in 46 per cent. cancer, was found. In 52.5 per cent. the extirpation was followed more or less immediately by death. Other 15 per cent. of the patients died from recidive or metastases within eighteen months after the operation. A patient, operated upon by Professor Kroenlein, of Zurich, four years ago, was still enjoying best health at the time of the communication. Four patients were found in perfect health when examined two years after nephrectomy, two twelve months after the operation, three six months, and one five months. In the remaining surviving cases, no information could be obtained beyond several weeks after the extirpation.

The intra-peritoneal method seems to be attended with greater danger than the extra-peritoneal one, the mortality amounting to 58 per cent. in the former case, against only 24 per cent. in the latter. Local recidives, however, are by far more frequent after extra-peritoneal nephrectomy (71 per cent.) than after intra-peritoneal (5 per cent.)

Progressive General Paralysis in Women.—At a recent meeting of the Medicinische Gesellschaft in Basel, Dr. Greppin has read notes (*Correspondenz-Blatt fuer Schweizer Aerzte*, August 1st, 1889, p. 466) on twenty-six female cases of progressive general paralysis, admitted to the Basle psychiatric clinic (the proportion of female cases of the disease to male in the clinic being 1 to 2.41). As regards the etiology, the first place was occupied by mental or physic overstrain, the second by climacteric changes. Heredity was elicited in fourteen patients, a syphilitic history in four. Sixteen patients belonged to working (indigent) classes, ten to well-to-do ones. As to the clinical forms of the affection, in twelve cases simple primary progressive dementia was diagnosed, in ten a maniacal variety, in three a mixed melancholic and hypochondric one, and in one hallucinatory paranoia. Fourteen patients died when in the clinic; seven were discharged, of them three in an improved state, but four without any amelioration. The remaining five are still under observation. The necropsy revealed the same morbid changes as are usually met with in male cases of general palsy. The microscopical examination invariably detected extensive proliferation of the cerebral neuroglia, degenerative lesions of ganglionic cells and blood vessels, and a marked wasting of myeline nerve fibres. The atrophy was most pronounced in the superficial layers of the cortical areas lying in front of the central gyri.

Dr. Greppin insists on a paramount importance of a possibly early recognition of prodromal symptoms of progressive paralysis, since when resorted to sufficiently early, an adequate treatment may often lead to gratifying results.

Antipyrine as a Uterine Anodyne.—Following Dr. F. Sielski's recommendations (*vide* the *Provincial Medical Journal*, February, 1889, p. 116,) Dr. J. Stepanoff, of Tomsk, West Siberia, has tried (*Meditzinskoïe Obozreniïe*, No. 12, 1889, p. 1159,) antipyrin (internally in one gramme doses) in two cases of uterine pain, and obtained excellent results. One of the cases refers to the author's wife, an exceedingly nervous and sensitive lady of thirty, in whom, on account of hyperemesis gravidarum abortion was induced in the third month of her fourth pregnancy. The fœtal membranes being retained in the uterine cavity, the uterine action became most violent and painful. Chloroform inhalations were kept up for four hours, but failed to bring about a permanent cessation of the patient's sufferings. It was then that the author resorted to antipyrin. In a quarter of an hour after the first dose, the pain subsided to cease altogether in an hour. Simultaneously all uterine bleeding (which had been almost incessant before) disappeared. Some pain recurring on the next day, another two doses, with the interval of four hours, were given, after which it ceased permanently.

Another case is that of a lady, aged twenty-eight, suffering from agonising dysmenorrhœa of several years' standing. Three doses of antipyrin, taken during the first day, caused a striking relief of the pain, lasting during the whole catomenial period. The patient who, on previous occasions, had been invariably lying in bed during the periods, could this time remain on her legs all through, and generally felt "happy," owing to the "marvellous powders."

Brachial Neuralgia caused by Pulpitis of Wisdom Teeth.—In the St. Petersburg odontological monthly, *Zübovratchebnyi Vestnik*, No. 2, 1889, p. 87, Dr. P. Tikhomiroff, of Tver, states that he repeatedly met with cases of severe brachial neuralgia following acute inflammation of the pulp of the lower wisdom teeth. He relates a case of a robust middle aged gentleman, with deep caries of the right lower wisdom tooth, in whom, during an attack of toothache, there suddenly supervened an excruciating pain over the corresponding side of the neck, shoulder, and along the whole upper limb. A considerable impairment of motor power of the extremity was also present. Suppurative pulpitis of the said back tooth was found. The extraction of the offender was followed by a rapid and complete disappearance of the neuralgia. The author adduces another case with identical particulars, the patient being a very anæmic young lady.

The Spirit of the Societies.

BRITISH MEDICAL ASSOCIATION.

LEEDS MEETING, AUGUST 13th to 17th, 1889.

[FROM OUR SPECIAL CORRESPONDENT.]

THE fifty-seventh annual meeting of the British Medical Association may be pronounced an unqualified success, both as regards the numbers who attended, excellence of papers, and arrangements made for the comfort and pleasure of the visitors. Great credit is due to the profession in Leeds, and to the citizens, for the hospitality they displayed. It sustains the Yorkshire reputation. Leeds is situated within easy distance of lovely scenery, so that one could escape in a few minutes from all that unloveliness which is really the source of the prosperity of Leeds—her manufactures, which are famous all over the world, and by which thousands are supported. The time will come when we shall have smokeless fuel, and then Leeds will be a changed city. Those who went to the garden parties, "at homes," balls, etc., were quite satisfied with Leeds as she was. The ticket salon on Tuesday presented a very animated appearance. As members arrived, they immediately sought the reception room, and here it was pleasant to see the greetings

between old friends who had not seen each other for years; so that if the Association had no other *raison d'être* it would find one in the bringing together annually of a number of old college friends, in the social intercourse which frequently ends in the establishment of new ones. The proceedings on the opening day were of an essentially business character. We are informed that the Council tendered an apology to Mr. Edward Owen for the editorial comment which appeared in the *British Medical Journal*, and which certainly reflected upon his honour. At the first general meeting the various reports from committees were passed with unanimity. The Bishop of Ripon preached an admirable sermon on "The Relations of Science and Religion," and as if to give a lie to the statements which are made that medical men, as a rule, are irreligious, there was a large attendance at the Parish Church. There was a goodly gathering in the evening at the Coliseum to hear the presidential address (abstract published at page 521). The resolutions passed on Tuesday were as follows:

1. On the motion of Mr. Rivington, seconded by Dr. Danford Thomas, the following resolution was unanimously adopted: "That it is the opinion of this meeting that the members of the Royal College of Surgeons of England should have a voice in the management of that College, and in the election of its Council, and that it be an instruction to the Council of this Association to further this object through the action of the Parliamentary Bills Committee, or of a special committee to be appointed for the purpose at this annual meeting." Dr. Ward Cousins hit the nail on the head when he said "that it might be right enough in the middle ages, but in the nineteenth century to exclude 12,000 members from any particle of power in their own College was monstrous."

2. In reply to a letter signed by Sir Joseph Lister as chairman, and Drs. W. H. Allchin, W. A. Meredith, John Williams, as secretaries, reflecting on the conduct of the *Journal*, the following resolution was passed with one dissentient: "Resolved that the Council do not admit that the signatories of this letter are better judges than themselves, or more solicitous than they are for the honour of the Association and of the profession; but if there are any points which the signatories desire to particularise, in which they consider that the *Journal* admits of or calls for improvement, they will—as they ever have been on receiving them through the representatives of their branches in the Council—be ready to give such suggestions their most careful consideration."

3. Resolutions of Mr. Brindley James and Dr. Rentoul were withdrawn, and the following substituted: "That the resolutions be referred to the Council of the Association; that the Council invite the branches and individual practitioners to forward suggestions to them; and that the Council furnish their report to the *Journal* within six months of the present date, and refer their conclusions to a general meeting."

4. The question of the payment of the travelling expenses of the representatives of the branches appears to come up perpetually at the meetings. What a change must have come over the members when they actually passed a resolution that travelling expenses in future should be paid out of the funds of the Association! The resolution was proposed by Dr. Ogilvie Grant, supported by Mr. Vincent Jackson, Mr. Brindley James, Mr. Lawson Tait, Dr. Jacob, Dr. Douglas, and Dr. Brierley. The opposition was very slight, and the motion was carried with a few dissentients.

The above resolutions indicate a change in the lines on which the Association has hitherto run. It indicates on the part of the Council a desire to act in accordance with the views of the majority, and to consider the general interests of the members. The Council is wise in moving in harmony with the spirit of modern times. The cliquery which at one time distinguished the Council no longer exists. This is due to the representative principle which now exists. The local journals published excellent accounts of the transactions from day to day, and I am indebted to the *Leeds Mercury* and *Yorkshire Post* for some of the matter which I send. The full reports published by these journals have, I think, a beneficial influence, and should tend to impress the public with the earnest way in which, in all branches of medicine, we are striving to advance.

SECOND GENERAL MEETING, AUGUST 14TH, 1889.

The second general meeting was held in the Coliseum in the afternoon, under the chairmanship of Mr. C. G. Wheelhouse (president), and was largely attended.

At the outset Dr. Bridgwater stated that the Council had not yet received any definite invitation for the meeting in 1890. Under the circumstances he had to move—"That it be recommended to the general meeting that the Council be empowered for the place of meeting in 1890, and for appointing of a President-elect.

Dr. Bristowe (St. Thomas' Hospital, London), seconded the proposition, which was adopted.

Dr. J. Hughlings Jackson, F.R.C.P., F.R.S. (Physician to the London Hospital, and to the National Hospital for the Epileptic and Paralysed), gave the address on "The Comparative Study of Diseases of the Nervous System." He said he did not advocate the application of the doctrine of evolution to the classification of diseases for practical purposes, but believed, nevertheless, that its indirect value to clinical medicine was very great indeed, and that before long it would be directly helpful. Thinking that for clinical purposes they must continue to have arrangements of cases "by type," he once more urged that they should also attempt a parallel study of diseases as they were dissolutions—that is, reversals of evolution. He would give a series of illustrations of his method, because it was one he followed largely in his address. A patient of his had lost one hand, but as was most often the case, he had representing it a phantom hand; this was always in position as if encircling a vessel; the member had been blown off when he was holding a cylinder to be charged with an explosive. An aphasic patient frequently uttered on being questioned, but with no relevance to anything going on, "Come on" or "Come on to me"; he was a signalman, and had been taken aphasic and hemiplegic on the railway in front of his box; the presumption was that he was saying, or was about to say, those words when taken ill. An epileptic patient told him that his first fit occurred when he was a soldier, and at the very time he was "numbering off"; after every subsequent fit, and before regaining consciousness, he used to count. A woman he was asked to see in a surgical ward in the London Hospital, who had fractured her skull by a fall when laying down oilcloth on a staircase, kept, during partial unconsciousness a few hours before death, manipulating the counterpane of her bed. They supposed that to be a sort of continuance of the action of laying down the oilcloth; the patient desisted for a time at least, when the nurse assured her that "it was properly laid." These illustrations would appear incoherently grouped to those who do not happen to see that the intention in stating them was not to deal with aphasia, epilepsy, and injury to the head, but to make a basis for the discovery of the reason why there was a fixation of states, which were normally temporary, upon the sudden occurrence of lesions of the nervous system. Very different cases were chosen in order to make the basis a broad one. This was by way of illustration, but he hoped that such facts were of some value towards the methodical study of persisting delusions. He suggested, quite hypothetically, that some very grotesque delusions might be a fixation of absurd beliefs in dreams, in cases where a sudden morbid change, or sudden increase of it, had occurred in the brain during sleep—such delusions as one mentioned to him by Dr. Savage. A patient of his believed himself to be a jar of Indian pickles. In the doctrine of evolution they had principles which no doubt applied to the whole organism, and to every one of its diseases; it was at once a means of scientific classification, and a guide to the discovery of new facts. The full symptomatology of a case of ocular paralysis was not to be intelligently stated even, unless activities of healthy centres, including the highest, were considered; and a case of insanity was not properly analysed unless undiseased parts of the highest centres and all lower centres were considered. In the two cases a great part of the symptomatology was owing to over activity of perfectly healthy nervous arrangements; the erroneous projection and diplopia in the first, and the illusions, delusions, and all other positive mental symptoms in the second. To insist on the principle implied, he said in recapitulation that every case of nervous disease was a problem, not only in dissolution but in evolution; in example, he who was studying the physical process during an illusion in an insane patient was as certainly dealing with evolution as he was studying that process during the perception of a healthy person. Before giving particular illustrations of dissolution he made brief statements concerning some different aspects of the one process evolution, of which dissolution was the reversal: (1) Evolution was a passage from the most to the least organised. "Highly organised" was frequently used synonymously with "vero complex;" but by degrees of organisation he meant degrees of perfection of union and certainty of action of nervous elements with one another. Using the term organised in that sense, he said that the highest cerebral centres were the least organised (the most helpless centres") although they were the most complex, whereas the lower centres were the most organised, although the least complex. In other words, they might say (2) that the evolutionary ascent was from the least to the most modifiable. If the highest centres were not modifiable, we should be very simple machines; we should make no new acquirements. If the lowest ("vital") centres were to become as modifiable as the highest, life would cease. It was only another aspect of this statement—that the progress in evolution is from the most to the least organised—to say (3) that the passage was from the most automatic to the most voluntary (properly, "to the least automatic"); equivalently it was (4) from structures inherited most nearly perfected (acquirements of the race and of prehuman beings), such as the cardiac centres in the

medulla oblongata (some centres of the lowest level of evolution)—from those comparatively perfectly evolved at birth—to those of the highest nervous arrangements of the highest centres, which were only incipient nervous structures, and which were evolving during the latest new mental states; (5) the process of evolution was from the simple to the complex; (6) from the general to the special. Reversals of evolution were effected by pathological processes, and were called dissolutions; they were reductions from the least organised, etc., towards the most organised, etc. Some, presumably all, cases of insanity illustrated dissolution. In Dr. Savage's important work, "Insanity," where he dealt with general paralysis, he wrote: "That the disease affects first the highest intellectual and motor acquirements is undoubted." He said, too, "Both Dr. Maudsley and I have independently taught that in this progressive degeneration the last and highest acquirements fail first." They had very good illustrations of dissolution in the symptomatology of drunkenness. Long ago Charles Bell wrote: "It is a fact familiar to pathologists that, where debility arises from affection of the brain, the influence is greatest on those muscles which are, in their natural condition, most under the command of the will. We may perceive this in the progressive stages of debility of the drunkard, when successively the muscles of the tongue, the eyes, the face, the limbs, become unmanageable; and under the same circumstances, the muscles, which have a double office, as those of the chest, lose their voluntary motions and retain their involuntary motions; the force of the arms is gone long before the action of breathing is effected." Lauder Brunton in his "Pharmacology" wrote: "In the action of such poisons as alcohol, the nervous system appears to be paralysed in inverse order of its development; the highest centres going first, next the middle, and then the lowest. After this comes paralysis of the motor nerves, and, lastly, of the muscles themselves." Dissolution was exemplified in each of the following exceedingly different symptoms: 1. Most epileptiform seizures began in the right thumb or index finger, or in both; these digits were the most special parts of the body. 2. The words most often left to an aphasic who was, for the rest, entirely speechless, were "yes," or "no," or both; these "words were the most general of all propositions. 3. The aphasic might be unable to put out his tongue when told, although he moved it well in other ways; loss of the "most voluntary" movement, with persistence of the more automatic movements of that organ. 4. In what was called word-blindness, there was inability to recognise the latest learned and very arbitrary "objects," letters and words, whilst the recognition of objects properly so-called was unimpaired, or comparatively so. 5. In early stages of atrophy of the brain, say in that occurring so often after hemiplegia in men past middle age, there was defect of memory for recent events with seemingly good remembrance for long past circumstances, and there was at the same time loss or defect of the "finest" latest acquired emotions, with obtrusion of the coarser and earlier acquired. Different as these five examples were they were alike in that dissolution was definitely illustrated by each of them. Opinions differed vastly as to who were the men of greatest mental elevation. Some would put Napoleon highest, others Shakespeare and Goethe. But evolution supplied us with a scientific measure, which ignored superior and inferior, as these terms were ordinarily used with regard to men's minds. That measure was according to the intellectual and emotional differences between lower and higher races of mankind, and to those between children and adults.

Higher races of men and adults had the latest acquired faculties, and these, according to Spencer, were, intellectual, the power of abstract reasoning, and, emotionally, the sentiment of justice. So that instead of saying that a person was superior or inferior to most other men, we might say that he had more or less of the latest faculties of the race than most other men had. He by no means thought that to have the latest intellectual faculties most highly developed was the same thing as being most endowed intellectually. The poet inherited in some ways more of the earlier acquired faculties of the race, and had less of the latest than the scientific man had; yet no one would say that poets were mentally inferior to scientific men. Ignoring the term voluntary, on account of its psychological implications, and using the term special, he said that the arm was the most special part in the cerebral series, and failed first in disease of the brain proper; and that the back was the most special part in the cerebellar series, and fails first in disease of the cerebellum. He then went on to contend: By aid of the doctrine of evolution they would discover a harmony or rational parallelism between (1) psychology, (2) the anatomy and physiology of the nervous system, and (3) that important part of clinical medicine which dealt with diseases of that system.

Dr. EDDISON (Leeds), in moving a vote of thanks to Dr. Hughlings Jackson for his address, said he doubted whether such a complex question had ever been put before an audience with greater clearness.

Dr. BRISTOWE seconded the resolution, which was carried.

THE STEWART PRIZE.

The PRESIDENT said that the next piece of business must be gratifying to all of them. It had passed into the minds of some men who took an interest in that Association to leave a permanent record of that interest; and among others they had had no man who had had the interest of the Association and of his profession more at heart than the late Alexander Patrick Stewart. Dr. Stewart had shown that interest was not evanescent by leaving behind him a record in the shape of a sum of money, the interest of which was given annually to gentlemen who were believed to have done the best work of the year in the study of the prevention and treatment of epidemic diseases. This year the prize of £50 had been awarded to Dr. Edward E. Klein, F.R.S., for his very valuable and prolonged researches in micro-organisms, and especially for work in connection with the etiology of scarlet fever. Addressing Dr. Klein, the President said that the prize was not given in the way of compensation for the time, labour, and money he had spent in his researches, but such as it was he hoped Dr. Klein would accept it at the hands of the Association as the gift of an old and dear friend who had passed away from them and who had left it at their disposal.

Dr. KLEIN, in returning thanks, said he took it that the honour was conferred on all those who were engaged in research which had for its object the dealing with epidemic diseases. He regarded it not merely as an acknowledgment of his own services, but as a recognition of the services which that particular branch of work—bacteriology—had rendered to medical science in general.

The PRESIDENT announced that representatives were in attendance from Sydney, Jamaica, as well as New York, Baltimore, and other parts of America.

THIRD GENERAL MEETING, AUGUST, 15TH, 1889.

THE ADDRESS IN SURGERY.

The third general meeting of the members of the association was held in the Coliseum. Mr. C. G. Wheelhouse, president of the association, occupied the chair.

MEDICAL OFFICERS OF HEALTH.

The CHAIRMAN said he had been desired to inform them of a resolution that had been passed in the Public Medicine Section, and to ask their sanction to it:—"August 14th, 1889.—Resolved, that the best thanks of this meeting be tendered to the Parliamentary Bills Committee for their action in reference to the appointment of medical officers of health, that the committee be requested to continue their labours in the matter, and that in the English Local Government Act a clause should be inserted providing that no medical officer of health should be dismissed from office without the consent of the Local Government Board, and also, that in regard to the appointment of any such officers, the word 'shall' should be substituted for 'may' in the English Local Government Act." The resolution was unanimously sanctioned, and the president thanked the meeting for their help. The Chairman then called on Mr. T. Pridgin Teale, M.A., to deliver his address on

"DETAIL IN SURGERY."

Mr. TEALE, who had a cordial reception, said that happily his immediate predecessor, in devoting his address to a review of the surgery of the last half-century, had set him free to choose a subject more congenial to his habit and work. He hoped to show how much some of the triumphs and shortcomings of modern surgery were made or marred by the carrying out of detail—detail which was essentially the embodyment of principle, not the mere multiplication of points of practice such as might not materially further the end in view. In working out this line of thought he hoped to be able profitably to employ the time at his disposal, and to give prominence to conclusions which had been formed during a surgical life of over thirty years, made up not of his own work alone, but very largely of the freest inter-change of thought and experience with most friendly and active-minded colleagues, medical and surgical, with whom it had been his great happiness to be associated. In so doing it had been his endeavour to be as little egotistical as was compatible with the attainment of the end in view. He dealt first with the question of division of an artery between two ligatures. The division of an artery in this manner, he said, recently revealed to him more fully than he had ever realised it before the immense elasticity of the arterial coats, as the separated ends receded fully half an inch from one another. The question at once occurred to him, could it be right ever to tie an artery by a single ligature, and to leave this powerful force of elasticity to work for ulceration of the coats and gaping of the ulcer, with the risk of final disturbance by retraction of the divided ends when ulceration had completed its work? Might they not here find an explanation of the

numerous failures of ligature of the great arteries of twenty and thirty years ago, and of the fatal secondary hæmorrhages, chiefly from the distal end? And were they to recognise and act upon the fact of the elasticity of an artery, or were they to ignore it, and to place their patient at the mercy of elastic drag, tension, ulceration, retraction when liberated, and secondary hæmorrhage? Did it not also involve the larger principle of "rest" as an important factor in the healing of any tissue? He next dealt with the instruments used in the treatment of stricture, showing the superiority of that known as "Lister's sound," the invention of Sir Joseph Lister, and passed on to what he termed "effective drainage." This he defined as the provision for the escape of secretions—whether by position of openings, shape of opening, or by use of drainage tube—from cavities before they had time to putrefy, and for their reception into one of the aseptic absorbent materials with which surgery was now so abundantly provided. Passing to the question of ether *versus* chloroform, he said it was a subject on which he wished to speak with a sense of grave responsibility—the more so that he had to express views which were strongly opposed to those uttered at Glasgow last year by his predecessor in that chair. If anyone asked why he ventured to differ so widely and strongly from one whose surgical experience was probably not less than his own, and might be greater, his plea was as follows:—"For the first fifteen years of my surgical life, which includes ten years as surgeon to the Leeds Infirmary, I knew little of any anæsthetic but chloroform. So far, probably, our experience runs parallel. During the last fifteen years ether has almost superseded chloroform in my practice. Here the parallel ceases. Sir George Macleod's second fifteen years are still devoted to chloroform. He cannot speak from fifteen years' experience of ether. As a result of the comparison of these two periods, I unhesitatingly assert that ether is, for safety to the patient and for comfort and convenience to the operator, immeasurably the better anæsthetic of the two." Mr. Teale then went on to say that his earliest experience of ether was in the method introduced by Dr. Joy Jeffreys, who, at the International Ophthalmic Congress in 1872, preached his crusade against the almost universal use of chloroform, and called attention to the fearfully increasing fatality of chloroform. They responded to his call, in spite of the great disadvantages of the clumsy, wasteful, nay, harmful method of giving ether by lavishly pouring it into a cone formed of a towel, to which Dr. Jeffreys introduced them. The struggling of the patient, the icy coldness of the inhaled air, the saturation of the air of the room with ether, and the not infrequent and occasionally fatal bronchitis which followed, were such obvious drawbacks that the wonder was that ether survived as an anæsthetic in England. He then described the gradual improvements in the administration of ether: the introduction from America, by the Rev. E. Spencer Gough, a late Chaplain of the Leeds Infirmary, of the wicker grid; the invention of the inhaler by Ormsby, of Dublin; and its development into its present form by Clover. There were many hospitals in England, and still more, he believed, in Scotland, where the use of ether was practically unknown, or where, if ether was given, the obsolete towel or the grid, or the very inferior inhaler of Ormsby, was used; or even should the hospital possess a Clover it might not possess an etherist who knew how to use it to the best advantage. To administer ether badly was to bring it down nearly to a level with chloroform as to safety, and to render it inferior to chloroform as to comfort to the patient. A bad etherist would cause fear, coughing, sense of suffocation, and other distressing symptoms to the patient, and would take five to ten minutes in getting him under the anæsthetic; would use twice or thrice at much ether as was needful; would keep his patient overcharged; and would, now and then, set up a dangerous bronchitis. A good etherist would win the confidence of his patient, and would, in nine cases out of ten, have him ready for operation in two or three minutes, and not infrequently in about a minute and a half, without a struggle, without coughing, often without even a transient sense of suffocation, and with the expenditure of about half an ounce of ether; and would but need about one ounce of ether for each quarter of an hour that the anæsthesia was kept up. In such a case they need fear no danger at the time, nor subsequent bronchitis. The advantages to the operator were also very great. In the first place, his anxiety was less, his fear of a fatal issue less, and when obliged to trust to an inexperienced administrator, as he must do at times in sudden emergencies, he could more efficiently keep an eye on the patient's condition, and superintend the administrator, than when chloroform was used. In the second place, there was a saving of time, a patient being brought under the influence of ether in two or three minutes, whereas chloroform, in his experience, needed eight or ten, and such a saving was of no slight moment in modern hospital practice now that the sphere of surgery had become so enormously extended. In the third place, under ether, return of consciousness to pain generally lagged behind the return of mental perception, and thus anæsthesia could easily be re-established without interrupting the operation. So marked was this fact towards the end of a prolonged operation, that sometimes the surgeon might continue to operate for ten minutes or a quarter of an hour without re-application of the inhaler, and even converse with his patient whilst stitching up a wound. This was hardly, or rarely, the case with chloroform. He next dealt with surgical instruments of various kinds, indicating the best shape and make, and making suggestions for their improvement. In conclusion, he said that those who had expected to hear a triumphant record of the astonishing progress of surgery, or a pæan on their local surgical achievements, might be disappointed at the humble theme which he had attempted to work out, and might think he had failed to do justice to colleagues who had done much to leave a mark upon the progress of surgery. His aim had been, not to sound the praise of individuals, much as they deserved it, but rather to leave an impression on the practice of surgery.

Mr. MACEWEN (Glasgow) moved, "That the best thanks of the British Medical Association be given to Mr. Teale for his very able address on surgery."—Dr. MITCHELL BANKS seconded.—Both gentlemen spoke in flattering terms of Mr. Teale's attainments as an operating surgeon, an oculist, and a pioneer in sanitary science. The vote was heartily carried, and Mr. TEALE replied.

NOTICE OF MOTION.

The following notice of motion was given by Dr. RENTOUL, of Liverpool: "That this general meeting of the British Medical Association views with great pleasure the action of the Charity Organisation Society of London in presenting a petition to the House of Lords praying for an inquiry into the management of the Metropolitan Medical Charities, and earnestly hopes that the scope of the enquiry will be extended so as to include the provincial hospitals and dispensaries, and thereby obtain as complete information as possible upon this important subject. That a copy of this resolution be forwarded to the Lord President of the Privy Council, and that he be requested to receive a deputation thereon; that the Council be requested to appoint a special committee to deal with this question, and to request the Charity Organisation Society of England to form a similar committee to act in conjunction with it."

LAST GENERAL MEETING, AUGUST 16TH, 1889.

ADDRESS BY SIR J. CRICHTON BROWNE ON MEDICAL PSYCHOLOGY.

The concluding general meeting of the members of the association was held in the Coliseum. Mr. C. G. WHEELHOUSE, President of the Association, occupied the chair.

The PRESIDENT called on Sir James Crichton Browne to deliver his address on

THE HYGIENIC USES OF IMAGINATION.

Sir JAMES CRICHTON BROWNE said it was clear that a large amount of labour and solicitude in connection with the supervision and treatment of those afflicted with insanity or diseases of the mind fell upon the main body of their profession. But the 84,407 insane persons who were in asylums of one kind or another on January 1st last, and under the care of specialists, had all been consigned to these establishments on the evidence of medical men who were not specialists. The Lunacy Acts Amendment Bill, which was awaiting the Royal Assent, would, when it become law, to some extent relieve medical men from the apprehensions which had hitherto attended the signing of lunacy certificates but no Act of Parliament could in any way diminish the sense of responsibility attending a step, entailing deprivation of freedom, some opprobrium, and far-reaching disabilities; and the certification of the insane must therefore always remain an anxious duty to general medical practitioners, and bring home to them the truth that they had an immediate concern in medical psychology. The disinclination of medical men of late years to sign lunacy certificates, while it had had, perhaps, some deplorable results, it had this advantage, that it had led to an extension of the system of treating the mentally afflicted under private care, and had taught their profession that much might be done outside an asylum to alleviate and dissipate mental derangements. About the supreme importance of the early treatment of insanity there could be no question, but that did not necessarily imply removal to an asylum, a course which should not be resorted to hastily or prematurely—not until it was clear that such was unavailing to stem the gathering torrent of medical perturbation; for it was possible that it sometimes converted slight into severe insanity, stereotyped the infirmity, or created a tendency to its recurrence. In the performance of his daily duty, medical psychology met the general practitioner at every turn, and its relation to nervous activities must necessarily engage his attention to some extent. Directing their attention more particularly to a mental faculty that had certainly no narrow local habitation in the brain—to imagination—he impressed

upon them that this physical power had its hygienic uses, which neither the medical psychologist nor general practitioner could afford to neglect. Imagination awakened and called forth from their organic registers in copious currents the records and movements and sensory impressions. Imagination might be spoken of as a pioneer opening up new pathways in the brain, or as a mode of transit between its territories. The brain that was without imagination was like a country without roads or railways, in which locomotion was laborious and slow; and the brain richly gifted with it was like one in which steam and electricity had established easy and rapid communication.

Primitive imagination had been simple and direct, but the imagination of highly civilised races was intricate and circuitous. He did not propose to say anything about the operation and influence of the imagination when resting on intuitive beliefs and historical facts; and stirred by the most earnest cravings of our nature, it mounted into faith, and revealed to them "the substance of things hoped for, the evidence of things not seen." It would be neither expedient nor possible for him to trace out there the bearings of faith on corporeal and mental welfare, nor must he even pause to bestow the notice they deserved on those excrescences on faith known as faith-healing and Christian science, which had a certain vogue at present, and fell legitimately within the scope of medical inquiry. Regarding these, he would just say that a close scrutiny of their literature could not fail to create a painful impression. It was not to be gainsayed that faith, even in its aborted or degenerated phases as monstrous or dilapidated superstition, had a potent effect on the human organisms, and was capable of relieving and removing certain functional disorders; and credit might therefore be given to faith-healing and Christian science for some of the cures which they claimed. Their professors, like empirics of all sorts, had wrought modern miracles on hypochondriacal men, who had fallen into drivelling egotism; on hysterical girls who had entertained demons not unawares, and on a few sincere but highly sensitive persons who could pass at a touch out of one allotropic state of the nervous system into another. But the small good they had done these had been more than counterbalanced by the mischief they had wrought in encouraging imposture, in postponing medical treatment where it was needed, and inducing in their adherents an attitude of mind that was debilitating and conducive to the incursion of disease. Before faith-healers and Christian scientists could claim a hearing, they must learn how to make an accurate clinical report, apprehend what induction really meant, and abandon the baseless assertions in which they at present dealt. Only impatience and contempt came to the medical man who perused their pretentious archives of cures in cases which disease was evidently simulated, in which it ran its natural course, in which its existence was asserted, no proof being given, or in which it was of a purely subjective character, and might or might not depart at the word of command—such archives being, in one or two instances, accompanied by minute directions as to how post-officer orders are to be forwarded. Let the faith-healers and Christian scientists commence with skin diseases—woo the olcarus scabei from its burrow without aid of brimstone, arrest lupus, and wipe out a nævus, and we shall then be ready to follow them with some hope in their campaign against hidden maladies. Was it not a little anomalous that, while palmistry and astrology—which were, at any rate, ancient and picturesque forms of superstition—were strictly suppressed, the peculiar people should be allowed to carry on their practices without police interference unless it could be shown that a life had actually been sacrificed to their blindness? Would it not be well that the benevolent busybodies who, with an audacity commensurate with their ignorance, assailed the unimpeachable scientific conclusions of Pasteur, should transfer their attention to a class of persons who were really performing painful experiments on living animals, to those faith-healers who, by their well-meant but futile inunctions, protracted sufferings which, in many instances, medical aid would speedily relieve? But his theme now was not faith-healing or faith—which faith-healing travestied—but the secular imagination and its hygienic uses, his aim being to convince them that it was one of the most effectual of those psychical agencies by which they might modify the conditions of health and disease.

The scientific use of the imagination in relation to medicine might be properly included in its hygienic uses, for that faculty was the main instrument of discovery in their investigations, both as regard the specific maladies of their patients and the nature and affinities of disease generally. As medical men, they had not merely to identify and catalogue the symptoms of disease, but they had to trace them to their antecedent and true causes, and this they could only do by invoking imagination's help to supply them with speculations and hypotheses, which were not less essential to them in their work than the microscope, test tube, and clinical thermometer. All true science rested on imaginings, and was, strictly speaking, a body of established truth which imagination had built up. Observed phenomena had to be explained by unfolding their causes; and in medical inquiry, as in common life, a provisional guess was hazarded, which was then put to the test by further observation and experiment. Of course such provisional guesses were often wrong, and have to be dismissed. But all the most adamantine truths of science had been provisional guesses to begin with—provisional guesses furnished by imagination, and proved by the touchstone of experiment, and so brought to more than mathematical certainty. The cultivation of the imagination then—and it could be cultivated and disciplined to agility and steadiness of action—was of high importance to them as medical men, and they need not fear that they were altogether wasting their time when they turned aside now and then from their professional tasks to ramble for a little in the green pastures of literature, or climb the pinnacles of art.

True, their imagination might be fully trained for its professional duty, as it was exercised, in conjunction with observation and judgment, in the scientific sphere; but it would be braced, invigorated, and have its resources multiplied by recreating occasionally in its native air. Even if, when indulged in moderation, imaginative pursuits did not strengthen the hands of medical men in grappling with disease, or quicken their scientific vision, these would still be commendable, because of the refreshment they bring to jaded brains. To turn from the fatigue and anxieties of practice into realms where rivalry were no more, and night bells never rang, was to plunge into one of the most soothing and depurative of "tired Nature's" baths. Members of their profession were, he suspected, generally aware of this, and resorted to imaginative literature, music, and art more than any other class of professional men, except, of course, artists and men of letters, and to an extent that was remarkable, considering the engrossing claims made on their time and the scant leisure enjoyed. Having referred to some of the by no means insignificant contributions of medical men to the department of imaginative work, Sir James Crichton-Browne remarked that it was not as producers, but as consumers of poetry and imaginative literature that medical men derived from them their restorative influence.

It might be objected that the imagination, if sometimes stimulating and restorative in its influence, was often morbid in its tendencies, and that its indulgence was to be guarded against by those who desire to possess well-regulated minds. But the weak vessels wrecked by imagination were really fewer than was commonly supposed; and he did not hesitate to say that for one case of insanity caused by excess of imagination, there are a dozen caused by the want of it. Apathetic dulness and torpor of mind were apt to deepen into dementia; and those entirely given up to "the care of this life and the deceitfulness of riches" were more likely to be choked by them than those who could surmount them, and breathe the free and ample air of æthetical emotion. A vulgar error as to the nature of insanity had perhaps conduced to exaggeration as to the dangers of imagination. Visitors to asylums invariably arrived expecting to find growths of morbid invention and belief, wild, tangled, and luxuriant as a tropical forest, and left much disappointed by the barrenness of the land, for the insane were the least imaginative of beings. Idiocy was the absolute negation of imagination, and insanity undermined and destroyed or enfeebled it more or less; and, when they drive out insanity, the first thing they did was to invoke imagination's aid, for moral treatment consisted mainly in appeals to this faculty, and fully acknowledged its hygienic uses. The first recorded cure of melancholia was by the harp of David, and to-day, in every lunatic hospital worth the name, persistent efforts were being made by music, by pictures, by poetry and the drama to stimulate the imagination, and thus "cleanse the bosom of that perilous stuff that weighs upon the heart." Like every good gift, imagination might be prostituted and abused, and, in the history of art, literature, and the drama, abundant proof might be found that it had been made to pander to vice and folly. But, when this had been the case, it was not so much the imagination that had been at fault as a certain pestiferous element that had been infused into it. The records of crime, when reported with prurient detail, and with a halo of romance thrown round them, had sometimes a permanently pernicious effect, and tended to reproduce themselves. Men of taste and delicately reared imagination turned from such garbage with disgust, but there were always sickly and partially depraved natures ready to be powerfully affected by strong impressions of a criminal complexion. Sheer weakness and vacuity or instability of temperament are the soils most congenial to vicious and atrocious ideas. A highly and widely cultivated imagination seems to increase physiological resistance to morbid and profligate suggestions, and also to pathogenic germs, for in plague and pestilence those are most likely to escape who have varied mental resources, can distract their minds and look beyond the moment, and those are most likely to escape who give themselves up to abject fear.

Having alluded to the undoubted enormous and progressive movement that had taken place in the purity of our literature and of the drama, Sir James Crichton Browne pointed out that the preservation of our

juvenile literature from any taint was of paramount importance, for impressions made on the imagination while brain development was actually going on were only indelible, but highly influential. That the craving for works of fiction was not only great but growing might be deduced from the statistics of public libraries, the amount of light literature produced, and the fact that newspapers now formed syndicates to supply their readers with a modicum of fiction. To them as medical men it was interesting to remark that this appetite was most urgent in spring, when nervous erithism existed, and "a young man's fancy lightly turns to thoughts of love"—and was least pressing in autumn, when the nervous system was comparatively quiescent. In conclusion, he repeated the assertion that imagination must always receive primary consideration in a study of mental hygiene.

Dr. NEEDHAM (Gloucester) moved a vote of thanks to Sir James Crichton Browne for his address. In doing so, he remarked that medical psychology had attained a position which entitled it to be placed on very much the same platform as general medicine.—Dr. RINGROSE ATKINS (Waterford) seconded the motion, which was carried by acclamation.

THE METROPOLITAN MEDICAL CHARITIES.

Dr. RENTOUL (Liverpool), in accordance with notice, moved the following resolution:—

"That this general meeting of the British Medical Association views with great pleasure the action of the Charity Organisation Society of London, in presenting a petition to the House of Lords praying for an inquiry into the management of the Metropolitan Medical Charities, and earnestly hopes that the scope of the inquiry will be extended so as to include the provincial hospitals and dispensaries, and thereby obtain as complete information as is possible upon this important subject. That a copy of this resolution be forwarded to the Lord President of the Privy Council, and that he be requested to appoint a Special Committee to deal with this question, and to request the Charity Organisation Society of England to form a similar committee to act in conjunction with it."

Mr. HART (London), in seconding, remarked that the question concerned not only, and chiefly, medical men, but the general public and hospital managers. He believed the course recommended was thoroughly practical.

Mr. ARTHUR JACKSON (Sheffield) and Surgeon-Major INCE spoke on the motion. The latter said the subject bore not only on the management of hospitals, but the more delicate question of the exclusion or segregation of out-patients. There was a feeling that many of those who applied to hospitals and dispensaries were not fit recipients of the bounties of those institutions. It was the custom in some hospitals to charge the out-patients for medicine, which he considered was a reflection on their profession.

The proposition was then agreed to.

Several resolutions passed by the Public Health Section were afterwards reported, and were referred for consideration to the Parliamentary Bills Committee.

VOTES OF THANKS.

The PRESIDENT remarked that they had been entertained in the handsomest manner by a large number of persons in Leeds. He proposed that votes of thanks be passed to them.

The motion having been carried, Dr. J. W. COUSINS (Portsmouth) proposed that the President be thanked for so ably presiding over the annual meeting, and for his continued exertions in the interests of the association.

The motion was carried with acclamation, and the proceedings terminated.

SECTIONAL MEETINGS.[1]

PUBLIC MEDICINE.

THIS section sat in the Philosophical Hall under the presidency of Dr. Edward Ballard, F.R.S., Medical Inspector, Local Government Board.

MEDICAL OFFICERS OF HEALTH.

Dr. BALLARD opened the proceedings of the section by reading a paper on "Medical Officers of Health: Their Training and the Conditions on which they should Hold Office." The subject, he said, was one which had been brought into prominence by a recent statute, and by the promise of further legislation in the same direction. It was clear that there was abundant room for the expression of both professional and non-professional opinion as to what should be further done, and what the relation shonld be between County and District Councils and their respective sanitary officers on the one hand and between the latter and actual sanitary authority of the kingdom on the other hand. In considering the requisites for a good and efficient medical officer of health it was evident that first he must possess himself of due learning. What he meant by that, of course, was that his mind must be specially stored with that kind of learting which should fit him to deal with and to advise about disease, not as it affected the individual but as it affected the community. It went without saying that, as communities were made up of individuals, a knowledge of disease as it affected individuals was the basis of the knowledge of disease as it affected communities; and this was the reason why an officer of health to be efficient must be a medical man. No knowledge came amiss to him. He had to deal often with complex problems, to solve which his mind could not be too well furnished, and furnished with information that the ordinary practitioner of the healing art had little or no call for, including such branches of knowledge as meteorology, geology, sewer and water engineering, the construction of houses, the ventilation of private and public buildings; or, to pass to living things, bacteriology, the subtle and often tortuous path of epidemic contagion, the physical and sometimes moral peculiarities of race, or the diseases of animals lower than man in the scale of creation, but domesticated for his use. When medical officers of health were first appointed in this country the necessity for special knowledge was scarcely recognised; but a considerable step was made in recognising this—that an officer of health should be a medical man. As he spoke that day the necessity for special knowledge had obtained recognition by Parliament. This was another great step in advance, ann not only so, but in the great schools of medicine in England, Scotland, and Ireland, provision had been made for giving requisite instruction. Secondly, to make a man an efficient health officer he required to be trained. The requisite science he might be taught, but the art was only to be acquired by practising it and by watching others practise it. It was the same with preventive as with curative medicine. The physician did not learn his art in the lecture room, but in the hospital; so the health officer learned his, either slowly and laboriously, with many mistakes and even some blundering in striving to carry on his duties, or he might take the shorter road of acting, working practically under the direction or supervision of another. He hoped that at the next session of the Medical Council some regulation pertaining to this subject would be formulated. Lastly, he might mention "tact"— an acquisition of rare value, but one the possession or lack of which might make all the difference between the successful and the inefficient medical officer of health. Deficiency in tact was a fault chiefly observable among the junior members of the confraternity. Anxious to serve their district, earnest and enthusiastic, they chafed at obstacles which they found impenetrable, and were ready to give up a strife which, over and over again, terminated in their discomforture. It was men of this stamp (and they were not always –he said it with bated breath—young men) that he heard perpetually calling out for central interference. They forgot that they were advisers, not administrators; that good and proper as their advice might be, there might be difficulties not apparent to them in at once pursuing it. A medical officer of health was not an autocrat; it was never intended that he should be one. Often and often it had happened that health officers, who had made this mistake, had sought his condolence with them in the tribulation they had thus brought upon themselves. They all got from him pretty much the same advice, which was to be patient, to bear with the infirmities of their weaker and less intellectual brethren, and keep their own consciences clear amidst all discouragements by carrying out their duties to the best of their ability, and leave other people to look after theirs.

Dr. G. E. J. GREENE (medical officer of health, Ferns, Ireland) contributed a paper which was read in his absence. He though that the chief reason why a medical officer to a dispensary district in Ireland, who was also a medical officer of health, was frequently found to perform his sanitary work in an imperfect manner was because it was often financially to his advantage to be "sanitarily amaurotic," especially when he who permitted a nuisance to exist was a well-to-do patient. Medical officers of health should possess a diploma in sanitary science, obtained by passing a Government examination in analytical chemistry, botany, geology, pathology, and sanitary engineering; should hold jurisdiction over a large area; he appointed by and draw their pay from Government, which pay should be sufficient to support them without their engaging in any other occupation; should not engage in private practice; and should have the option of promotion to a better district after some years service. The Parliamentary Bills Committee of the British Medical Association might have a bill embodying some of these practical points introduced next session into Parliament.

Dr. GRIMSHAW (Registrar-General of Ireland) wrote saying that had he been present he had intended to advocate a system of organisation of public health officers on the Irish system. He was strongly in

[1] *Leeds Mercury*, August 14th, 15th, 16th, 1889.

favour of combining in one person the offices of poor-law officer, public vaccinator, district medical officer of health, and registrar of births and deaths. Such a civil medical service was the foundation upon which the whole State medical system should rest; only there should be independent offices, say for counties and groups of unions. There should be inspectors, then superintendent officers for counties, and then again the really active officer who combined all the offices together. He thought a local officer should not require so high a qualification as the county officer or the combined Union officer.

Dr. CALDWELL SMITH (Glasgow) pointed out that under the Scotch Local Government Act medical officers of health in Scotland had attained some tenure of office, and could not now be dismissed without the consent of the Board of Supervision. That, of course, was a very great point, and he thought the meeting should memorialise the Government that next year the English Local Government Act should have a clause embodying the same principle.

Dr. LITTLEJOHN (Edinburgh) was of opinion that a medical officer should not be bothered too much with chemistry. Chemistry had made such advances in the past few years that it was impossible for a man engaged in sanitation to complete with a chemist on his own ground. He should certainly be qualified to advise on adulteration, but that was sufficient. He supported Dr. Smith's view with regard to tenure of office, and said that what they chiefly complained of was the miserable salaries given for sanitary duties. The Chairman's remarks on tact could not, he thought, be too heavily emphasised.

Alderman EMSLEY (Leeds) disagreed with the proposal to take the power of dismissing the medical officer from the Corporation or the local authority which employed him. In Leeds they had not found that the Local Government Board had done in many instances what the Corporation with the advantage of local knowledge thought was the only thing that could properly be done. At present the Leeds Corporation was trying to get at the cause of the high death-rate, and it was probably that ultimately they would either have to move for an Act of Parliament or else take action under the Artisans' Dwelling Act. In his opinion the difficulty would have to be met as Birmingham had met a similar difficulty by taking large areas and securing their improvement. There was another point on which he was sure the Corporation of Leeds, and probably other large towns, would like to have the advice of the section—the subject of river pollution. The River Aire at present was simply a vast sewer. Whatever Leeds endeavoured to do to prevent pollution from the town itself was unavailing, because higher up there were the towns of Bradford, Shipley, Apperley Bridge, and many other towns, all of which poured refuse into the river.

Dr. ALLFREY (St. Mary Cray, Kent) said he was perfectly satisfied that it was absolutely necessary that a medical officer, if he intended to do any good at all, should be independent of private practice. He thought the plan of organisation suggested by Dr. Grimshaw was the best that had yet been devised.

Mr. A. DE'ATH (Buckingham) contended that as the Local Government Board now very wisely supervised the work of the vaccination officer it would be desirable that the same supervision should be exercised over medical officers of health and local authorities.

Dr. WHITELEGGE (Nottingham) said that medical officers ought to be able to form a common-sense opinion based on an ordinary knowledge of the subjects of chemistry, engineering, and Acts of Parliament bearing on their duties, and they should decide on most of those points for themselves. The one qualification that was essential was a familiarity with infectious diseases, and he warned them that in dealing with matters of that kind public opinion was too emotional to be taken as a guide. He supported the view that the tenure of office should be subject to the control of the Local Government Board, and he held that it would be unwise in any way to relax the control of that Board.

Mr. BRINDLEY JAMES (London) considered that the training of the medical officer of health was a very important factor. He should be properly trained. Every medical officer should be apprenticed, and should study the various branches of science connected with sanitation, and should be well up in chemistry and the applied sciences. He should hold office for life, and should not be allowed to practice as a general practitioner.

Mr. W. HOLDER (Hull) thought pupilage was becoming as necessary in all branches of the profession as it was in the old times. The office of medical officer of health was comparatively new, and he believed that some Corporations had not yet been fully educated to recognise the benefits that were to be derived from the office. He should not like to think that any man could be appointed for life.

Surgeon-Major POOLE (London) advocated the selection of medical officers from the general body of medical practitioners, instead of, as was the tendency at present, from the ranks of specialists.

Mr. OGILVIE GRANT (Inverness) and Dr. GREENWOOD (London) continued the discussion.

Dr. BROWN (Bacup) read a paper in which he argued that there ought to be appointed by the L.G.B. an officer who was well able to train men in their work. The conditions on which medical officers now held office were scandalously unsatisfactory. If faithful in the discharge of their duties they might have to resign, to submit to reductions in their salaries, and to other petty annoyances. Salaries should be fixed by the central authority at a fixed minimum in all large districts, though for County Councils this might not be absolutely necessary; and there should also be a fixed minimum of increase for every five or seven years. This would be conducive to the best interests of the people.

Dr. BALLARD, replying on the discussion, said it did not follow that because the Irish system was successful in Ireland it would suit England. In his experience he found that local authorities very often did not appreciate a man as a medical adviser but simply as an inspector of nuisances, which was not the position of a medical officer at all. He was quite sure that that section would not wish in any way to advise or suggest anything in the present condition of the medical affairs of Leeds. It was only general principles he thought on which they could say a word. One point raised by Alderman Emsley was that of cutting up a large town into small districts, and giving to the medical officer for each a small salary. That idea would never do either in Leeds or any other large district; unless a medical officer had time and opportunity to progress he was almost useless. The rivers pollution question, he thought, was dealt with under the new Act.

Dr. CALDWELL SMITH moved the following resolution :—

That in the English Local Government Bill a clause should be inserted providing that no medical officer of health shall be dismissed without the consent of the Local Government Board, and also that in regard to the appointment of medical officers the word "shall" should be substituted for "may" in the Local Government Bill.

Mr. LOE (Leeds), seconded, and the resolution was adopted. It was also agreed to thank the Parliamentary Committee for their efforts to secure the recognition of the principle, embodied in the resolution, when the bill was before Parliament.

A CABINET MINISTER OF PUBLIC HEALTH.

Mr. J. BRINDLEY JAMES read an address in which he advocated the establishment of a civil medical service of the Crown. We had Ministers of Commerce, of Public Works; the Post Office was represented in the Ministry, but no recognition of the medical profession itself had ever existed officially in England. What was needed to constitute a proper medical administration—not necessarily a complex one—was the creation of two medical peers—one a distinguished consulting surgeon, the other an eminent physician—and a Cabinet Minister of Public Health, with the prospect of a similar distinction on retiring from his office, his appointment thereto being based absolutely on his professional eminence and abilities alone; in no way on his political sympathies. These might appear startling proposals, but it should be remembered also that while the Bar and the Church offered the prospect of attaining the highest State distinctions, Medicine alone had always been Cinderella of the three learned sisters—quite as useful and comely, but unrecognised by "the world." Disease and death were no respectors of persons, striking alike at Pharaoh on his throne and at the bondsman at his gate; it was clear, therefore, that the sanitary state of the public was as much a State interest as public finance, war, commerce, or agriculture. Moreover, the Bar and the junior branch of legal practitioners had each their hierarchy culminating in high officials of the Crown, who efficiently maintained their professional etiquette and dignity, able to promptly expel unworthy members of the profession from its ranks; the purity of the Church was protected in a similar manner, and was likewise represented in the House of Lords; but the medical profession, which expected each of its members to prove himself alike a scientist, a practitioner, a philanthropist, and in every sense a gentleman, had no real executive to maintain its standard and protect its interests. Two medical lords would ensure it a due amount of Parliamentary supervision, and forcibly benefit the whole community, if only forcibly suppressing quackery. But their existence would avail little without the creation of a Minister of Public Health, absolutely independent of any political consideration whatsoever, as in private life we entrusted our relatives' lives to the most able practitioner, whatever his tenets, political or religious. His tenure of office should, therefore, be unaffected by change of Government, and he should be entrusted with full powers of selection, promotion, or removal of all public officers of health, whose personal fitness and personal interest his own Ministerial would fully guarantee, while a peerage would prove a fitting reward at the close of his career. To his arbitration all points of medical ethics, all questions relating to medical education and examinations, should be referred, and the whole control of the curriculum should be entrusted to him and the two medical peers concurrently. The abstention of all public medical officers of health

of course implied compensatory salaries, but the gain to the people at large in health and longevity would render this expenditure true economy. Finally, it should be an essential condition that all future candidates for vacancies in this "Public Medical Civil Service" should have served a previous apprenticeship under some one of their predecessors, under conditions regulated by the Medical Minister assisted by the two Medical Lords. Might they hope these suggestions would be ultimately endorsed by the time-honoured professional injunction "*statim sumenda?*"

No dicussion arose on the address.

IMPURE MILK AND TYPHOID FEVER.

Dr. A. M. Anderson (Medical Officer of Health, Dundee) sent a paper dealing with a "Peculiar teat-eruption in a milch cow with an outbreak of typhoid fever among the consumers of the milk." From facts which were quoted the writer concluded that the spread of typhoid fever infection among the persons using milk from the infected diary was greatly checked owing to measures which were taken to renew and trap a drain leading from the cowshed to the main sewer in the street which had been found to be defective and untrapped. The cow, too, was isolated from the rest, since when it had been milked by the cattleman, who did not milk the other cows, and its milk had been used for feeding young calves, none of it being sold or distributed to the public. Having regard to the incubation period of the disease, he thought it might be fairly maintained, although not conclusively proved, that eight cases of typhoid fever which occurred between April 15th, when the measures alluded to were taken, and May 15th were caused by infected milk consumed prior to the former date, and that the milk was wholly non-infectious after April 15th.

Dr. Caldwell Smith did not think that Dr. Anderson had proved his case. He was afraid that, what with typhoid and scarlet fever, the poor cow was going to have a bad time of it, and he urged that, instead of fixing primarily upon the milk as a cause of the cases mentioned, other things ought to have been taken into consideration as well.

SANITATION IN LEEDS.

Dr. Churton (Physician to the Leeds General Infirmary) contributed a paper on "Results of a Systematic Inquiry into the Sanitary State of the Homes of Hospital In-patients," which was read in his absence. The inquiry was undertaken in order to ascertain the possible share which insanitary conditions at home, and especially defective drains, might have in the causation of diseases of medical in-patients. The author, in his paper read at Glasgow last year, had estimated that approximately one-fourth to one-third of hospital patients had grossly insanitary homes, and he then remarked upon the unwisdom and costliness of sending patients back to the bad conditions from which they came, and which had helped to make them ill. It was not practicable to investigate the homes of patients who came from the country, but only of those living in the borough of Leeds. At first the cases for investigation were selected, the addresses of those patients only being taken whose diseases or histories seemed to warrant the suspicion that something was wrong at their home. Of these fifty-three houses were examined; twenty-eight were found defective. Cases were next taken from the medical and ophthalmic wards, without any reference to the nature of the ailments—the house of every patient living in Leeds being examined—of these there were 435; eighty-one houses were found to be defective. It thus appeared, with respect to in-patients, that about one house in five was in a distinctly insanitary state. The defects were mainly want of traps to the sink-pipes and broken drains. Occasionally an exceptionally offensive privy was the ground of complaint; sometimes a good condition within the house was counter-balanced by an offensive gully, exhaling gases from the street drains, within three feet of the front door. The examinations were made by the sanitary inspectors of the borough. A list of the Leeds patients was sent weekly or fortnightly to the sanitary office, and by the kind co-operation of the Medical Officer of Health (Dr. Goldie) and the Sanitary Superintendent (Mr. Newhouse), the inspections were at once made, and reports furnished. Although the ophthalmic cases—many of them simply accidents, and without disease of any kind—might have increased the number of healthy houses inspected, the comparatively low ratio of defects was a pleasant surprise. Personal investigations made during eight years (ending in 1885) among patients of the Leeds Dispensary had prepared the author for a much worse result; but he had not realised to the full the efficiency of the work of the sanitary authority, and the quiet reform which had been gradually taking place, house by house, from one cause or another in the borough. But there still remained much to be done when 20 per cent. of all the houses inspected appeared to be unsound. It had been shown that the reporting of patients' addresses to the sanitary officers was a very easy matter, and their inspections could not fail to be of service to the patients, and eventually to the hospital. It was hoped that the experiment, which would be continued as long as possible at Leeds, would be tried at some other hospitals also. One great advantage resulting from this inquiry had been that 109 houses (containing about 500 persons), which otherwise might have remained defective, had been put into a perfectly sanitary state.

Mr. R. C. Appleton (Beverley) was strongly of opinion that bad bye-laws had much to do with the bad health of large towns. He cited the Kirkstall Road part of Leeds as an example of spacious and well-ventilated streets, which might well be copied by other large towns.

Dr. Roberts (Keighley) gave some particulars of the sanitary work which had been accomplished in Keighley in recent years.

The section then adjourned.

* * * *

The section of Public Medicine again met in the Philosophical Hall.

The President (Dr. E. Ballard, one of the Medical Inspectors of the Local Government Board) occupied the chair. The attendance was larger than on the previous day.

DISINFECTION WITH REFERENCE TO THE CONTROL OF EPIDEMICS.

Dr. Parsons (formerly Medical Officer of Health at Goole, and now an Inspector of the Local Government) read a paper on the above subject. He said that by disinfection he meant the destruction of infection, the destroying of the activity of that matter which, produced by a sick person and received into the system of a healthy one, had the power of causing in the latter a disease similar to that from which the former was suffering. Modern research has shown that certain diseases in men and animals were undoubtedly caused by the presence in the system of micro-organisms that were communicable by the inoculation of such organisms. It was in most cases not practicable to test directly the effects of their disinfecting agents upon the contagia of the ordinary infectious diseases of mankind, for the reason that they could not make the necessary experiments (including control experiments with undisinfected portions of material) upon human beings, and these diseases could not, or could not with certainty, be produced by inoculation in the lower animals. If, however, they chose the most refractory organism pathogenic to animals that they could find, and ascertain how it might be killed, they would be tolerably safe in assuming that the same means would kill the contagia of the infectious diseases of mankind with which as sanitarians they had to do. Now, certain of the pathogenic micro-organisms, bacilli, had the property of forming spores, and these spores were found to be more resistant than the fully developed organism, just as a grain of wheat would survive treatment, such as drying and dipping in poisonous solutions, which would kill a growing plant. Of the pathogenic microbes the most convenient for the purpose of testing disinfecting agents was the bacillus anthracis. It formed under certain circumstances spores which were exceedingly tenacious of life; it could be cultivated, and was easily recognised both by its microscopic character and its appearance when growing and if inoculated into animals it produced in them with certainty the disease known as anthrax. None of the infectious diseases of mankind were known to be caused by spore-bearing microbes, though it was possible that small-pox, the contagium of which was very tenacious of life, may turn out to be so, and so far as their present knowledge and experience went, they might assume that means which would destroy the spores of the bacillus anthracis might be relied on as efficacious for their purpose, though it did not follow that agents which did not destroy the bacillus anthracis were therefore useless against the less resisting contagia of other diseases. An extensive and important series of researches upon the efficacy of disinfectants, conducted by Koch and his coadjutors for the German Imperial Board of Health, was in large part the foundation of our modern knowledge on the subject, though his results had been confirmed and extended by other workers, as Dr. Klein in this country, and a committee of the American Medical Association in the United States. Carbolic acid was found have a powerful restraining effect upon the growth of bacteria, but was much less efficacious in destroying their vitality. To kill spore-bearing forms, it was necessary to steep them for one or two days in a 5 per cent. watery solution; a 2 per cent. solution only killed them at the end of a week, while a 1 per cent. solution did not kill them in fifteen days. Solutions of carbolic acid in alcohol or oil had not the smallest disinfecting effect; a 5 per cent. solution did not kill spore-bearing bacilli, however long they were exposed to its action. Vapour of carbolic acid at ordinary temperature had no destructive effect on spore-bearing bacilli, though some effect was produced at elevated temperatures. In other cases, also, it was found that the disinfecting effect of substances in the form of vapour was increased by elevation of temperature; thus, spores of bacilli in garden earth were killed in two hours by exposure at a temperature of 176 degrees Fahr. to the vapour of bisulphide of carbon, although neither a temperature of 176 degrees Fahr. in dry air, nor the vapour of bisulphide of carbon in equal concentration at ordinary temperatures

had any destructive action at all on them. Sulphurous acid gas was found efficacious for the destruction of non-spore bearing organisms. Exposure to one part in 100 of air killed micrococci, if dry, in twenty minutes; if moist, in one minute. Spore-bearing forms, however, were not killed even after fourteen days' exposure to a 6 per cent. gaseous mixture of sulphurous acid gas in air. Chloride of lime had no disinfecting effects; spores of anthrax bacillus which had remained for a month in a 5 per cent. solution were in no way affected. Experimenting with heat in the dry form, Koch found that bacteria free from spores could not withstand an exposure of one and a half hours to a temperature a little over 212° F. in hot air, but that spores of bacilli were only destroyed by remaining three hours in hot air at 284° F. He also found that in hot air the temperature penetrated so slowly that after three or four hours heating to 284°F. articles such as small bundles of clothes and pillows were not disinfected, and that by heat of this degree and duration most textile materials were more or less injured. The results with steam were strikingly superior. It was found that an exposure of five minutes to steam at 212° F. was sufficient to kill the spores of the bacillus anthracis, and that the penetration of the heat into articles exposed to steam took place far more rapidly than into the same articles exposed to hot air. A series of experiments made by Dr. Klein and himself confirmed, on the whole, these results of Koch. The materials experimented with were spore-bearing cultures of anthrax bacillus, anthrax blood free from spores, bacilli of swine fever, and tuberculous pus, and the results were tested by inoculation on animals. Their results were more favourable to the efficacy of dry heat than those of Koch. They found that spores of bacillus anthracis were killed by exposure for four hours to a temperature between 212° and 216° F., or for one hour to 245°. Non-spore bearing bacilli were rendered inert by one hour's exposure to 212° and 218° F. Anthrax spores were killed by boiling for a minute in water, or by exposure for more than five hours to steam at 212° F. They also found steam heat to penetrate far more rapidly than dry heat. Similar results had been observed by other observers, so that the superiority of steam over hot air as a disinfectant might be looked upon as thoroughly established. Burning, of course, was a very thorough means of disinfection. It was characteristic of the class of infectious diseases that the morbid poison which produced disease multiplied in the body of the patient, and was given off again from it, and that it continued thus to propagate itself for a considerable period, often for several weeks. The poison was believed to be especially given off from the part of the body upon which its local effects were manifested, as from the skin in smallpox, the skin and throat and perhaps the kidneys in scarlet fever, in discharges from the throat and nostrils in diphtheria, and from the bowels in enteric fever and cholera. There was reason to think also that the contagia of some at least of these diseases could multiply in suitable media outside the body, as in milk, sewage, soiled linen, or moist sewage, contaminated soil; perhaps, also, even in potable water. On the other hand, some of the pathogenic organisms were found to perish as putrefaction advanced, either through the formation by them of chemical compounds antagonistic to their own life, or through the competition of the ordinary putrefactive forms, just as in a neglected garden the exotic flowers were choked or stifled by rank growths of the indigenous weeds. Contagia were not as a rule permanently destroyed by cold, though that of yellow fever was so. They also, in general, were able to survive drying, though Koch states that drying was fatal to the comma bacillus which he finds in Asiatic cholera. The matters which may act as carriers of infection, and might thus require disinfection, were: (1) The body of the patient, living or dead; (2) the discharges given off from the body of the patient, and more particularly those from the organs specially affected by the disease; (3) the air tainted by exhalations from the sick, and the poison probably existing therein in the form of suspended particles; (4) the clothes, bedding, and other textile articles used by the sick; (5) utensils of various kinds used by the sick; (6) articles of food, as milk and water; (7) walls, floors, etc, of dwellings occupied by the sick, especially dust and dirt lodging upon the walls, and dirt accumulating in the cracks of the floor; (8) collections of filth, as sewage, especially in a stagnant state, or deposited in, or encrusting the sides of foul drains, foul ground surfaces, and subsoil. It was not of much use attempting to disinfect the infected air of sick rooms by chemical means, for active chemicals, if present in sufficient quantity to be effective as disinfectants, would render the air irrespirable. It was easier to get rid of it, and let its place be taken by fresh air. The contagia of most infectious diseases appeared to be destroyed when fully diluted with fresh air. The poison of typhus fever was notably so, but that of smallpox did not appear to be, as Mr. Power had shown that smallpox might be disseminated through the air for considerable distances around a hospital in which many cases of that disease were under treatment. To avoid this it had been proposed that instead of ventilating smallpox wards into the open air, the air from them should be extracted through a flue and burnt in a furnace; or he might suggest that a steam blast might be used to extract the air and disinfect it at the same time. Of chemical disinfectants for the disinfection of excreta, corrosive sublimate was probably the most trust worthy and suitable for ordinary use. In its use, however, precautions had to be borne in mind, because it was very poisonous. After alluding to various other chemical disinfectants, Dr. Parsons said that with care, and in a suitable apparatus, most articles could be submitted to either dry or steam heat without serious injury, but leather was instantly destroyed by steam. Books, in these days of free libraries, sometimes wanted to be disinfected. It might be done by exposing them to dry heat, the covers being held back so as to open out the leaves, and allow the heat to penetrate. Steam was inadmissible, as it would soften the glue and destroy the leather. A process suitable for the disinfection of rags at paper and shoddy mills was a great desideratum, the requisites being that it should be cheap, rapid, and effectual, and applicable to rags in the bale without unpacking. For house disinfection, fumigation with sulphurous acid or chloric gas, the latter preferred, followed by thorough cleansing and scrubbing, the removal of wall-paper and lime-washing were to be recommended; but these processes, to be effectual, needed to be carried out with more thoroughness than was often done. A difficulty often met with was to know where the inmates were to go while the house was being disinfected, and it would be useful for this and other purposes if the sanitary authorities had power to provide refuges for people whom, although not themselves sick, it might be desirable to remove from their homes.

DISINFECTION AND ISOLATION IN THEIR PRACTICAL ASPECT.

Dr. CALDWELL SMITH (Glasgow) read a paper on "Disinfection and Isolation in their Practical Aspect." He remarked that disinfection and isolation, to be of any use at all, must be thorough and complete. It was his experience, and he was quite certain it was theirs also, that in the great majority of cases of zymotic disease the former had been carried out very inefficiently, while the latter was very frequently not carried out at all. Until disinfection and isolation were carried out with the utmost thoroughness, they could not hope ever to reach that milennium of preventive medicine when zymotic disease shall have ceased to exist. With regard to isolation in hospitals, he thought that in a large town the different zymotic diseases should be treated in separate pavilions, and no communication should exist between wards containing cases of different zymotic disease. In the case of the larger towns, the pavilion for small-pox should be situated at a distance from the other pavilions. He suggested that it should be at a distance of two or three miles from the nearest occupied dwelling, and surrounded by a belt of trees, but not sufficiently near to interfere with the free circulation of air round the building. In the larger towns there should be a separate resident medical officer, whose duty would solely consist in attending to cases of disease in the hospital. In the case of the smaller towns and the rural districts, provision should be made by means of cottage hospitals. Alluding to the question of disinfection in hospitals, he said that each hospital should, as a *sine qua non*, contain a steam disinfecting apparatus; a laundry should be provided at a distance from the hospital, and no communication should be allowed between those handling the infected and those handling the disinfected articles. He had known several cases of scarlet fever and small-pox in washerwomen in that way. As to disinfection and isolation at home, it was at all times a difficult matter. Among the poor it was absolutely impossible, and in cases of smallpox and typhus in all cases it should not be attempted. In cases, however, of scarlet fever, measles, diphtheria, and typhoid among the well-to-do, it might often be carried out fairly satisfactorily. Next—and this was more important in scarlet fever than in typhoid—there should be no communication between the nurse and any occupant of the house. It was, however, only in a few houses that absolute isolation could be got, and his opinion was that all cases of epidemic disease should at once be removed to a hospital. Noticing the question of home disinfection, he said they had yet to teach the public, and he was afraid the profession also, much. After a patient was convalescent, the floor, walls, ceiling, and the other solid articles in the room, should be washed with a disinfectant solution, the paper, if any, being removed and burned, and the ceiling whitewashed. The bed, blankets, and personal articles of clothing, should be disinfected in the steam disinfecting apparatus, and then washed. The room should then be thoroughly disinfected for a week before being occupied; and in his experience, which was now very large, those measures were always sufficient to prevent the spread of the contagion. Within the last five years he had attended over 1,500 cases of epidemic disease, and he had never been unsuccessful in preventing the spread of the disease from the patient after his attendance had begun, and so soon as his instructions were carried out thoroughly.

THE EFFECTS OF DISINFECTION AND ISOLATION IN THE CONTROL OF EPIDEMICS.

Dr. WM. SQUIRE contributed a paper on the above subject, and in his absence it was read by Mr. EASTES. The author stated that within the last twenty years only, or since the last meeting of this association at Leeds, we had had such means of isolating the sick in the more common epidemics as to enable a judgment to be formed of the success obtained, and of the parts due to each of various sanitary measures in producing it. The good effects of better drainage and pure water had been established, not only in the prevention of enteric fever, but in the diminution of phthisical disease, and some sanitarians were hopeful that epidemics of the more obviously infective fevers would be abated. This hope soon proved fallacious; even infections such as relapsing fever and typhus, thought to be the associates of filth and famine, reappeared in England very shortly, and in London a hospital for the isolation of relapsing fever was, in 1870, opened at Hampstead; more than 200 cases were received, and the disease rapidly disappeared from amongst us. In this same year, 1870, smallpox, spread by the Franco-German war, raised the fatality of this disease in London to 972, and in 1871 to 7,912, from what was then thought the low figure of 275 in 1869; only once, in 1857, had it been below 200. This sudden increase of smallpox occurred at the end of 1870, and from that time dates the permanent provision made by the Metropolitan Asylums Board for the isolation of infectious fevers; in two months 582 cases of small-pox were received into the board's hospitals, and during the next twelve months 13,145 were thus isolated; even then not half the fatal cases had been patients in these hospitals, but next year only one in nine of all the deaths from small-pox in London occurred out of the Asylums Board Hospitals. At length the means of isolations were adequate to the proportion of the epidemic, and the mortality from small-pox was reduced to 57 and to 26 for the two years 1874-5, or one-fifth of any previous minimum. This was before the ships were utilised as small-pox hospitals, and the reduction was not for one year only as heretofore.

Typhus, in the same way, after 1,071 cases had been isolated by these hospitals; was reduced in 1875 to 65 cases; in 1880 to 28 cases; in 1886 to 10 cases, and last year to one only, though twice in those ten years a tendency to increase had been observed. In those instances, and and in those from enteric and scarlet fevers to be noticed, isolation is not the only factor concerned. Disinfection has a large share in the control over the spread of those epidemics. The disinfection of premises, rooms, and clothes, which follows upon the removal of the sick, often prevents other cases arising from the same source, while the removal of the patient for the whole period of infection is a more efficient safeguard against its spread than any amount of soap and water or external disinfectant could possibly be. It may here be observed that the provision of mean of isolation by sanitary authorities and securing facilities for all classes to avail themselves of such means is equal to, and often more than equal to, any scheme for the registration of infectious illness, or for the notifying the outbreak of infectious diseases in large communities. Both means should be in force, but it is useless to give notice of the presence of infection unless means of isolation are provided and insisted on; no method of disinfection will succeed unless those who have been exposed to infection are kept from mixing with others, at school or elsewhere, until they are known to have escaped it, and those who have been attacked are kept from mixing with the susceptible until the infection period is over. Scarlet fever, against which we have no vaccinal defence, is specially in need of extended means of isolation; yet, until five years ago, before Miss Mary Wardell's home, we had no convalescent place for scarlet-fever patients, and the fever hospital at Islington could take but few of the numerous acute cases always occurring aronnd us. The Asylums Board Hospitals took in a gradually increasing number, but under many restrictions, and it was not until the epidemic of 1887 that more adequate provision was made. In the last quarter of 1887 close upon 3,000 cases of scarlet fever were treated in these hospitals, with a mortality of 257, or more than two-thirds of all the deaths in London from the epidemic in this the highest period of its activity; in this year 5,900 cases were treated in these hospitals, and 4,408 last year, all the convalescents being detained during the infectious period. Diphtheria is now dealt with in the same law. Consequently, in this 1887 epidemic, scarlet fever in London was less fatal than in many non-epidemic years, and so completely was it arrested that for the first time since registration began no autumnal increase of it occurred with us at the end of last year.

Dr. UNDERHILL read a paper by Dr. E. W. HOPE (Liverpool) dealing with the value of isolation. A number of instances were given showing that neglect to take proper measures for the isolation of persons suffering from infectious diseases led to serious consequences.

THE MANAGEMENT OF INFECTIOUS DISEASE IN HOTELS.

Dr. C. H. ALLFREY (St. Mary Cray) gave an account of the manner in which he dealt with an outbreak of scarlatina in an hotel at Grasse, near Cannes. Assuming the sequence of events to be as he explained, Dr. Allfrey laid stress on the importance of extreme caution in giving advice as to the infection from mild cases, holding that it is only safe to treat all cases, however mild and whatever their stage, as equally infectious, believing that infection depended more on the susceptibility of the patient and on the degree and circumstances of the exposure that on the severity or stage of the infecting case. He expressed an opinion that a second outbreak at the hotel would have been prevented altogether—certainly so far as the hotel was concerned—had the removal from the hotel of the whole of the infected family been insisted upon. He thought that the importance of adopting such a course upon similar occasions should be impressed upon all hotel-keepers. He advocated the formation of an association of hotel-keepers to ensure the sanitary well-being of hotels, having for its principal objects —(1) an agreement to insist upon the removal from their hotels (as soon as practicable and convenient with the safety of individuals) of all members of an infected family; (2) an agreement, as suggested by Dr. Burney Yeo, to require the signature of all visitors to a declaration that none of the party have been suffering from or, to their knowledge, exposed to infection within a certain period; (3) the establishment of a registrar of sanitarily certified hotels. The speaker advocated warmly the non-concealment of the occurrence of infectious cases, both as a matter of justice to the visitors and as a matter of policy to the proprietors. He believed that visitors in a hotel where existence of infectious disease was known, and where they could see that precautions were taken, and gauge the degree of danger, were, in point of fact, safer than in chance hotels, where cases of infectious disease might be concealed.

Dr. C. F. HUTCHINSON (Scarborough and Monte Carlo) said that he had charge of the epidemic of scarlet fever during the past winter at Monte Carlo. From the experience he then had he was convinced that the present way of disinfecting rooms after scarlet fever was absolutely useless. He could not guarantee that a room so treated was safe. There was no satisfactory way of dealing with scarlet fever except isolation in another building.

Dr. ASTON who said he had been medical superintendent of a hydropathic establishment for five years, suggested that in England no public establishment should be allowed to receive children as visitors unless they had satisfied the sanitary authorities that they were in a position to deal with an outbreak of infectious disease.

Dr. LITTLEJOHN (Edinburgh) remarked that one villa would be no use for the purpose of isolation. There would have to be several villas —one for scarlet fever, one for typhoid, and so on. There should be in connection with every centre of population an epidemic hospital. It should not, however, simply provide accommodation for the ordinary working-class portion of the community. There should be special accommodation for the well-to-do, with a seperate nursing establishment for them should be choose. In Edinburgh they lived on their visitors, and an epidemic in the hotels would have disastrous results. Special provision was made in the hospital for members of the upper classes, and they had Professors of the Univerity and Judges sending their families to it when they were attacked with infectious diseases. They could there be attended by their own medical man. (Hear, hear.) He was of opinion that there should be a room in connection with every hotel into which a visitor exhibiting signs of having contracted an infectious disease might be placed for observation or until a removal to the hospital could be affected. In Edinburgh they had compulsory removal and nortification in connection with infectious diseases. The hotel and lodging-house keepers favoured the system. It might be asked, Did not this interfere with the *amour propre* of the medical profession? Nothing of the kind. If the system had not proved satisfactory they would have heard of it long ago.

Mr. LOE (Leeds) said for some time he had been on the Sanitary Committee of the Leeds Corporation, and it had been his desire that there should be compulsary notification of infectious diseases in the borough. They had not, however, yet succeeded in getting it. His idea was that the duty of giving the notification should not rest with the medical man, but with the head of the family. He was satisfied that without notification isolation would be useless. As regards open drains in our towns, he said that in Leeds, with few exceptions, the drains were open. He was of opinion that drains should be closed. Ventilating shafts might be taken up the outside of buildings. He had known several cases of typhoid fever arising from open drainage. He should be glad to hear a strong expression of opinion in regard to compulsory notification from that meeting.

The PRESIDENT though they had better not go beyond the four corners of the subject they were discussing.

Dr. OGILVIE GRANT (Inverness) having made a few remarks,

Dr. GREENWOOD (London) said he had often wondered why the gullies in the metropolis had carbolic powder sprinkled over them. He supposed it was simply done to pander to the ignorance of the public. He had looked out for the same sort of thing in Leeds, and he owned with great satisfaction that he had seen none of it. He did not know whether it was because the rain had washed the powder away.

Dr. WHITELEGGE (Nottingham) remarked that small-pox could be crushed out by isolation, and scarlet fever could be got rid of very similarly. But he did not see how they were going to deal with measles satisfactorily in the same way. It was a delusion to imagine that they would have notification of all cases in which no medical man was called in. They would only get information of about a third or a quarter.

Dr. EASTES spoke in favour of isolation. He had had an experience in the parish of Paddington lasting over twenty years. Formerly diseases of an infectious kind were much commoner than they were now. It was almost impossible to isolate cases which occurred in rich families twenty years ago. Now, however, the case was different, and families were often only too glad for infected members to be sent away. During the last two years he had sent away members of large families, with the result that in no case had another member of those families contracted the disease.

Dr. HIRST (Prestwich) urged the necessity for the sanitary authorities in country districts having the power to remove patients to the hospitals.

Dr. MACLAURIN (New South Wales) said that the colony he came from had compulsory notification of smallpox both from the medical attendant and from the householder, sactioned by a heavy fine. When the disease was notified the Government authorities sent a man to relieve the practitioner of the care of the patient. The Government also insisted not only on the removal of the sufferer, but of every one who might have been brought into contact with the sick person.

Dr. EASTES.—The doctor as well?

Dr. MACLAURIN said that in one case the doctor was removed, but he was well compensated, as he received a fee of £3,000. That was many years ago. The isolation was continued until it waa thought there was no possible chance of the disease being spread. Although a large proportion of the population had not been vaccinated, smallpox was practically stamped out of the colony by the adoption of those measures.

Subsequently a small committee, which was appointed to draft a resolution embodying the views of these present about the treatment of outbreaks of infectious diseases in hotels, brought forward the following, which was moved by Dr. LITTLEJOHN and seconded by Dr. ALLFREY:—

That this meeting of the Public Health Section of the Brittish Medical Association recommends the formation by all keepers of hotels, hydropathic establishments, and boarding-houses in a town (or other convenient district) of an association for the mutual sanitary protection of themselves and visitors.

That this association should have for its principal objects—

(1) An agreement to insist upon the removal (as soon as possible, when consistent with safety) of all members of an infected family.

(2) An agreement to require the signature of every visitor to a declaration that none of his or her party has recently been suffering from any infectious disease, or has to his or her knowledge been exposed to infection.

(3) The establishment of a register of hotels certified to be in a perfect sanitary condition.

The section recommends that such certificates, which must be approved by the local sanitary authority, should be renewed annually after inspection, and that they should be exposed in a prominent position in every hotel and hydropathic establishment.

The section also recommends such a combination of hotel-keepers, that in towns where no sufficient provision for such purposes exists, they should themselves provide, either jointly or separately, a detached building for the isolation of infectious or double cases.

The resolution was carried unanimously, and it was further decided that it should be submitted to the general meeting for conformation.

THE TREATMENT AND DISPOSAL OF TOWN REFUSE.

Dr. GREENWOOD, of London, then read a paper on "Dusting in our Large Towns. He referred to the importance from a public point of view of an inquiry as to whether the methods of dusting now in use in our large towns were the best possible under existing circumstances; whether they could be indefinitely continued in the future, and what system would be the best to adopt (*a*) from a sanitary, (*b*) from an economic one. He noticed the evils arising from allowing putrescible waste to be stored in the midst of large towns, and the probability of a diminution of the death-rate consequent on a more rapid removal of house refuse. Reference was made to the advantages of the pail system, and to the necessity of covered vehicles for the removal of refuse. With regard to the disposal of refuse, it was here, he remarked, that they encountered their chief difficulties; it was here that the dictates of sanitary science and the dictates of economy seemed to be most hopelessly at variance. The refuse might be divided into the street sweepings and the house refuse. The proper place for the former would seem to be the soil, as it must contain considerable manurial properties; but as the value of this depends largely on the character of the road surfaces from which it was taken, very little profit at the present time seems to be attainable by its disposal, although from a sanitary point of view its admixture with the soil would be fraught with very little danger. With regard to the latter—viz., the house refuse—it was quite another matter. This had little, if any, manurial value. It was impossible to find a market for it in its crude state; and up to the present the dominating idea of Local Boards had been to get rid of it in the cheapest manner, frequently with utter disregard to the question of public sanitation. Shoots had been acquired, in many instances in improper situations, and refuse had been accumulated in sites that in a few years were notoriously to be built upon under the very noses of the sanitary authorities, and sometimes despite the complaints of ratepayers in the vicinity. The evils arising from houses built on made soil of this description were too well known to need comment, especially when they considered the character of much of the building of the present day, and the rarity of any attempt being made to guard against these dangers by concrete foundations. In the suburbs of the metropolis many houses had been built on such soil, and the health of the inhabitants must have suffered correspondingly. He knew of one house where swarms of flies used to rise up annually from the basement, and this might be pointed out as a tolerably good illustration of the organic purity of the subsoil. Similar evils are constantly occurring in the vicinity of all rapidly increasing towns, and it seemed to him that sanitarians should condemn and use every means in their power to prevent this contamination of the subsoil. Science pointed unmistakably to cremation as the only likely solution of the problem as to the disposal of their dead—a question which every year became more urgent, and which a future generation would be compelled to deal with; and none the less surely did it indicate, in his opinion, that the destruction by fire of their organic refuse was the best method of destroying its noxious properties, and rendering the after disposal of the products of combustion at least a harmless procedure from a sanitary point of view. Economically, it was probably at present more costly than the old rough-and-ready method of shooting the refuse in any hole or corner that could be cheaply acquired, regardless of the welfare of others; but this cheapness was by no means so certain now-a-days, when sanitary authorities were beginning to wake up to their duties, and when injunctions and legal proceedings on the part of aggrieved townships and individuals were apt to make a considerable hole in the profits that a not too scrupulous contractor might have been netting by improper disposal of refuse. As to the possibility of gaining pecuniary profit from their refuse disposal, that, he thought, got less every year. Summing up, he remarked that the present system of dusting was a faulty one, and not suitable for continuance; that in the present state of their knowledge a small portable receptacle ought to be substituted for the present large and immovable dust-bin, and that the refuse should be daily, or at very short intervals, collected, so that no accumulation be allowed near the houses of the people. The frequent practice of carrying the refuse through the public thoroughfares in open carts was greatly to be condemned, and the employment of covered vehicles for this purpose should be rigidly insisted upon. Lastly, with regard to the disposal, the whole of it, with the exception, perhaps, of some of the street sweepings, should be carbonised as a preliminary to its ultimate disposal, in order to destroy matters likely to give rise to future sanitary evils; and the present shooting into ground adjoining towns which were likely to be built upon at a not distant future was a practice much to be deprecated, as being fraught with considerable public danger.

Mr. J. BRINDLEY JAMES followed with a paper in which he dwelt upon—(1) The importance of rendering contamination of the surrounding soil by sewers impossible. (2) A chemical system of treatment and utilisation as manure of all slops, excreta, etc., with exception. (3) The contamination of all rivers, streams, wells, etc., prevented. (4) The total suppression of cesspools, and the prohibition by law of their construction. (5) Each householder to be compelled to burn his own vegetable refuse, and provided with dust-pails for periodical removal (as enforced in Bermondsey). (6) Last, but not least, the construction of a parish crematorium for the reduction to ashes, utilisable in themselves, of all refuse otherwise perplexing to dispose of. Fire purifies everything, and this system, easily rendered innocuous to those employed in it, would confer an incalculable amount of hygienic benefit on the public at large, whose adoption of the same cannot be too zealously invited.

In a paper upon "The Collection and Disposal of Refuse in Smaller Towns" (which was read by Dr. Eastes),

Dr. E. SLADE-KING (Medical Officer of Health for Great Torrington,

Ilfracombe, and Dulverton) said that the waste products of man's domestic life part themselves for sanitary purposes into two great divisions: (1) sewage, including all excretal and liquid waste; (2) house-refuse, composed of the more solid matters cast away as useless from human habitations, and of the waste materials resulting from the smaller trades and manufactures. House-refuse demanded the consideration of the sanitarian in three stages—namely, in its formation in and around houses; in its collection and removal; in its treatment and ultimate disposal. As to its formation or accumulation, cupboards, ashpits, and dustholes were condemned as unfit; and the use was advocated of galvanised metal vessels, casks, or boxes, coated with some non-absorbent material, light in weight, fitted with covers. The collection and removal should be done early in the forenoon, at intervals never exceeding four days, by the scavenger, who empties the contents of the ash-boxes one after another into his cart. Certain precautions were necessary to ensure that each householder does his duty by putting out the refuse in time for the collection. As to the treatment and disposal of house refuse, fire seemed the only effectual agent which could be employed for its purification and practical destruction.

THE PUBLIC CLEANSING OF TOWNS, VIEWED IN RELATION TO PUBLIC HEALTH.

Mr. D. Edgar Flinn, Examiner in Public Health, Royal College of Surgeons, Ireland, in the course of a paper on this subject, remarked that public cleansing is so very closely allied to public health that it is evidently one of the principal duties that urban and rural sanitary authorities should insist upon being systematically and properly carried out, for upon its efficient administration depends, to a great extent, the general health and well-being of a community. It is urgently incumbent on the authorities of each town and district to solve this important problem for themselves, and to find out how best to carry out this all-important work. The water-supply, the method of sewerage, and the habits of the population, are each and all of them more or less determining factors in the carrying out of a particular plan. No system of town cleansing can be maintained, or efficiently worked, unless it be undertaken by the sanitary authority; for, according as towns grow and dwellings increase, so much more difficult does it become for individual householders to dispose of their refuse. The immediate removal of all refuse and filth is the most essential element in the public cleansing of towns. Even to deposit refuse temporarily on the ground is dangerous, as the atmosphere of the dwelling-house is very much affected by the state of the atmosphere of the soil near it. If the soil near dwellings is allowed to become impregnated with refuse and filth, which is so often cast out of houses of the tenement order, the air must naturally become polluted, and will carry the germs of many diseases to houses at a distance. Public cleansing, then, cannot be too strictly enforced, and its thorough administration becomes year after year more apparent and more necessary for the health of the people and the prevention of disease. The daily door-to-door collection at a stated early hour each morning, by means of dustbins large enough to contain the dry refuse collected during the twenty-four hours is a system working well in a large number of towns, and is becoming generally adopted. It is certainly a vast improvement on the system of emptying all house refuse into an ashpit, in close proximity very often to the dwelling-house, where a fermenting mixture of excreta, vegetable refuse, and dust, is permitted to remain for a long period, creating a public nuisance and a danger to the health of a neighbourhood. The portable pail collection of house refuse should be enforced by every sanitary authority, and each householder should be supplied with these bins, a slight charge being made in the case of houses above a certain rating, and the poorer class of houses being supplied with them free of cost. Nearly all our great epidemics have their origin in the laneways, courtyards, and alleys of the towns, and these are the localities where cleanliness and daily scavenging should be systematically carried out. The cleansing of towns has a marked determining effect on the death-rate of a population, and it is notorious that wherever a regular and systematic method of cleansing is carried out, the rate of mortality is always comparatively low, and diseases of epidemic character are rare. To aid in the fulfilment of the benefits to be derived from public cleansing, the domestic cleansing of the houses of the people is a necessary adjunct, and they should be taught that the initial principles of sanitary work must commence in the individual house. The destruction of the first germs of disease is of the utmost importance, and it is to the homes of those resident in the courts and laneways of our cities and towns that the lesson should be taught that national health lies in the individual cleanliness and surroundings of the house and its inmates.

The last paper read was by

Dr. C. F. Moore (Dublin), who said that the disposal of town refuse and excremental matter has, since the visitations of epidemic cholera in 1854-66, and previously in 1849, occupied a prominent place in public medicine. He drew attention to the endeavours which had been made in this direction, the subject having become one of great importance by reason of the great increase of town populations within the present century. The subject embraced the great main-drainage system, the removal and utilisation or destruction of town refuse, and the treatment and disposal of excremental matter by other methods than that of sewers. The great objects of the latter is the disposal, without creating a nuisance or injury to the public health, of excremental matter in such a way, if possible, as to fertilise the ground. One great difficulty in carrying out the disposal of excremental matter by other means than by a system of sewers in many parts of these countries appears to be the absence of a class of persons who will faithfully discharge the duty in a thorough and effective manner. The Chinese and Japanese afforded examples of this mode of treatment of such matters of great antiquity and effectiveness.

In the course of the discussion which followed the reading of the papers,

Dr. Parsons said that stress had been laid upon the proper treatment of town dust. The observations were much more forcible when they had to deal with household dust mixed with excreta, as was often the case in northern towns. It was necessary that there should be an improved system of dealing with this refuse, in place of the midden, which held such a prominent place in the affections of some Yorkshire sanitary authorities. The collection of dust should be done on a regular plan. The cart should go round the district at known times, the dust being ready for removal in small water-tight receptacles, which ought to be emptied there and then. This would do away with the horrible plan of repeated shovelling up. It was not necessary, where middens were used, that they should be made large enough for a man to get inside. The London dust-bins were not. The bottom might be made to slope, so that the contents could be got out by using a long-handled tool.

The President said that he knew of no subject which could be more profitably discussed in Yorkshire than the disposal of town refuse.

Mr. Jessop (London) thought it would be well if they could make the householders responsible for the due removal of refuse.

Dr. Cameron (Medical Officer of Health, Huddersfield) did not think they had any right to insist upon householders telling the authorities when they ought to remove the dust. In every town there ought to be such a system in force that the dust bins were cleared before they became filled. There was, however, one way in which a householder could give considerable assistance to the authorities. It was by reducing the amount of material that was placed in the dust bin. In his own home he insisted upon all vegetable and animal refuse being placed at the back of the kitchen fire at night to dry, and then in the morning it was raked on to the fire and cremated. In that way and by the use of Mr. T. Pridgin Teale's economisers a wonderful revolution had been brought about in the quantity of material thrown into the dust bin. The typical plan of getting rid of the refuse would be to have it collected every day and taken away at once. It could not always be managed, but they should try and get as near to that ideal as possible. He should like to carry out a proper water-carriage system in regard to night-soil in Huddersfield. He hoped to have it in time.

Dr. Littlejohn said that the water-carriage system was followed to a large extent in Edinburgh. They had also the daily removal. He should like it to go forth from that section that it was high time that middens were done away with. They might do what they liked, but if vegetable refuse and other kinds of organic matter got into the dust bins, it would undergo a slow process of decomposition. The only remedy was a daily remedy; and if they could carry it out where there was a population of 260,000, they surely ought to be able to manage it in Leeds. In Edinburgh the removal was made once a day from the better-class houses, and twice a day from those of the poorer classes. The difficulties were no doubt increased when they came to sparsely populated districts. The trench system seemed to him to solve the difficulty. In all the small villages in Scotland they did their best to introduce the daily removal plan.

After further discussion, a committee was appointed in order that a resolution dealing with the subject of town refuse may be submitted to the section this morning before other business is proceeded with.

THE ANNUAL MUSEUM.

[LEEDS MEETING.]

There is always a difficulty in obtaining a room large enough to hold a number of exhibits, and near enough to the general meeting place. The annual museum is the general rendezvous. The room at Leeds was in an excellent position; but, unfortunately, it was not very large, so that the exhibits were not seen to the best advantage. The first

section—devoted to instruments, foods, etc.—was in the large hall in the Mechanics, and on opening the door the first stall that presented itself was that of **Messrs. G. & G. Stern,** who had on view all their pumiline preparations. The air around the stall was scented with the well-known essence. We may briefly allude to a few of the forms in which pumiline was exhibited.

1. **Pumiline Ointment.**—This at once attracted attention by its smooth and homogenous surface, promising to form a bland and soothing application for eczema, erythema, and for all inflamed and irritating surfaces. We learnt from Mr. Stern that the pumiline is combined with oleate of zinc, paraffin, and then thoroughly incorporated with lanoline, and that it has been thoroughly tested by some of the best dermatologists, who have reported very favourably on the results obtained from it.

2. **Pumiline Jujubes.**—These are tonic and astringent, of agreeable flavour.

3. **Pumiline Plaster.**—Messrs. St. Dalmas, Leicester, have prepared these plasters with 15 per cent. of the extract, and they form an excellent medium for applying the remedy. The pumilio pine, especially that growing in the Alpine districts, where the tree is stunted, possesses medicinal virtues, which have been admirably utilised by medical men at various continental spas. The finest essential oil is obtained from the most stunted variety, and it is to this oil which Messrs. G. and G. Stern have given the fanciful name of pumiline, and from which they make many of their preparations. The pumiline essence is a distillate obtained from the needles of *pinus pumilio*, and may be used in various ways by inhalation, embrocation, in the form of gargle, given internally in doses of two or three drops. The extract is obtained from the needles, and young shoots of the pine, and may be employed in the treatment of rheumatism and gout. Terebinthanates are too well known to need much elaboration at our hands. Amongst the purest of the pine products we must reckon the pumiline group.

Jeyes' Disinfectants.—We have for some years been accustomed to the use of Jeyes' disinfectant at the Halifax Borough Hospital, and we are perfectly convinced that it is an admirable disinfectant. We have used it in the various forms of soap, fluid, etc.

Sanitas Co.—Sanitas and Jeyes were close together. We have so recently alluded to the properties of the disinfecting preparations made by the Sanitas Company, that we need not repeat the opinion we have expressed on the value of the Sanitas preparations.

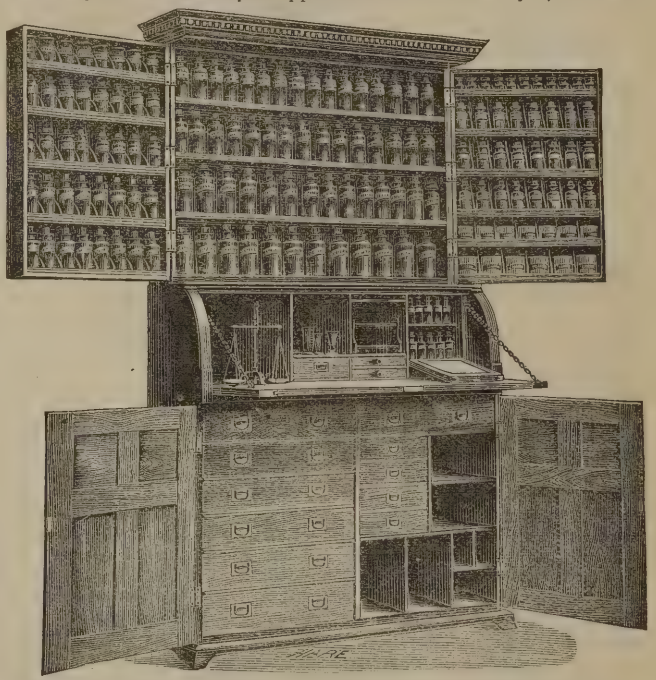
Hockin, Wilson & Co.—This stall was admirably arranged, and the instruments and drugs showed up well from the red plush background. We were particularly struck with the catheters, made from the best Belfast linen, which for finish and pliability are fit to compare with the best French catheters. These catheters are now extensively used, and give great satisfaction for their durability. The pharmaceutical preparations of Messrs. Hockin, Wilson and Co., included their well-known podophyllin compounds. These have now an established reputation, and are particularly serviceable for home dispensing, as they form in combination—owing to their ready miscibility—bright and pleasing mixtures of podophyllin, in combination with pepsine, belladonna, and strychnia. The other exhibits of Hockin, Wilson and Co., included a number of the usual surgical instruments carried by the practitioner, all of which were of excellent workmanship.

Hoff's Malt Extract.—The Hamburg malt extract is one of the oldest forms of the valuable preparations of malt, now so extensively used for the dieting of patients, and Messrs. Hoff are well-known exhibitors at the annual museum. Their samples are freely distributed, and this year he gave to all who visited a very handsome blotting pad and a small card case, and to ladies who showed an interest in their extract a very ingenious needle case. The extract is admirably suited for invalids who cannot take the thick malt extracts made by other firms. It is pleasant, invigorating, reconstituent, and well deserves the reputation it has acquired under the name of the Hamburgh Brand.

Champagne in Syphons.—Messrs. Carswell and Co., 32a, Piccadilly, London, had a novel method of bottling champagne, and their exhibit attracted a crowd of visitors. Champagne is very frequently ordered for the sick, but in the ordinary bottles there is not only great waste, but the wine loses in flavour and potency when once opened, no matter what form of contrivance we use. Messrs. Carswell have overcome the difficulty by putting up the champagne in syphons. This has been achieved after a series of experiments, and by using fittings capable of resisting acids. The syphon bottle is of the usual shape, but the metal fittings are coated with gold and silver, so that the wine is not in any way affected by contact. The advantages of the new system are very great; there is absolutely no waste. A glass of fresh champagne can be drawn at any moment, and the last glass comes out with as foaming a head as the first. The wine selected for bottling is a very dry brand of Camisole & Cie, of Epernay. It is a good, sound champagne, of excellent flavour and of reasonable price. The syphon was exhibited in a small casket, packed with ice, so that for the sick room it can be kept cool. We anticipate a very wide use for this system, not only for the purposes of the sick, but at clubs and refreshment rooms.

The Universal Digestive Tea Company.—From champagne to tea is a transition; but tea is so universally used, and some teas are so injurious, that it is well worth the attention of the medical men to know of a tea which can be recommended. It is well known that nervousness and indigestion are produced by the use as well as the abuse of tea. Most teas contain an excess of tannin, and we believe that to the tannin is to be attributed the injurious effects on digestion. The Universal Digestive Tea is a blend of India, China, and Ceylon teas, but by a patent process the tannin is rendered inactive. The tea has a delicate, pleasant, aromatic flavour, without any roughness; and it appears to us that this innocent beverage may be still more widely used, now that they have a tea which can be recommended as being free from any injurious properties.

John Richardson & Co., Friar-lane, Leicester—The Dispensing Cabinet.—This cabinet is certainly the most comprehensive, complete, and handsomest cabinet in the market. Constructed of best polished walnut, and made in the very best style, it is a handsome article of furniture. Its compartments are admirably devised, holding numerous bottles of various sizes, with drawers and divisions for almost everything that is required in the art of dispensing. Our first impression was that it was really too good, and that owing to its price would be out of the reach of many practitioners, but we learned subsequently that cheaper ones, of identical construction, could also be obtained, manufactured of polished pitch pine or stained deal, particulars whereof can always be obtained upon application. Unfortunately space could



not be given to it in the room devoted to pharmaceutical specialities, and it was separated from Messrs. Richardson's exhibit, which included nearly all their well-known preparations. Their colonists' chests and small medical field companions, fitted up with every requisite, attracted considerable attention, and were much admired. There were a large number of fitted cases suitable for practitioners in country practice, and by means of compressed drugs and pills these cases were made to hold a large number of medicines. The pearl-coated pills formed an attractive feature of this stall, and were to be seen in every conceivable form, shape, and colour. The Cascara Sagrada Lozenges are admirably suited to those who do not like any bitter medicine. The thymol preparations and soap are now standard specialities, and are gaining popularity. The same may be said of Richardson's other specialities, as exorrhoid, etc. We need not enter into further details as to the names of the specialities for which this firm is noted.

Brand & Co.—The dietetic specialities of this firm are very firmly established in the confidence of the profession. Their beef essences, jellies, bouillons, lozenges, biscuits, enable us to keep our patients alive when no other form of food can be taken. The Brand preparations are prepared with the greatest care in the selection of the animals from which the extracts, etc., are made, so that we can confidently recommend them to our patients.

The Sanitary Wood Wool Company.—Hartman's patent wood-wool wadding has for some time been before the profession, and is used in all the leading hospitals in the United Kingdom. Many improved forms have been introduced, aud we direct particular attention to the wood-wool sheets intended for confinements, etc., and to their wood-wool diapers and napkins for infants.

John Milne.—The antiseptic dressings introduced by this firm—the red cross brand—have now obtained a well-deserved position. The great development which has taken place in consequence of Listerism is largely due to Mr. Milne, and we are certainly indebted to him for the beautiful fabrics in which he now conveys to us the various forms of dressing. We have but to look at the long list of antiseptic dressings advertised by Mr. Milne to see the rich variety at our selection. The Alembroth dressings are an instance of the progress which has been made. Boracic acid dressings appear to be coming into more steady use. Surgeon-Major Burke has devised a first field dressing, which will be found extremely useful, the materials of which are supplied from the antiseptic dressing factory of Mr. Milne. We would direct attention to Mr. Milne's illustrated price list.

Messrs. Robertson & Co., Operative Chemists, 35, George-street, Edinburgh, had a much more extensive exhibition of their specialities than at the Glasgow Exhibition. This firm is evidently developing a very large capsule business, and judging from the quality of what was shown, they well deserve the success that is attending them. They showed a most complete range of their flexible gelatine capsules. As at Glasgow, they have a large display of ferruginous pill mass (Blaud's), and combined with extracts of nux vomica, aloes, and with arsenic, digitalin, and a variety of other powerful medicines. These iron capsules were originated by them, and there can be no doubt but that the principle for which they have obtained letters patent is a most valuable one. It consists in suspending the ingredients of Blaud's pill mass (alkali and ferrous iron) so that no reaction takes place until the capsules reach the contents of the stomach. In this way they exhibit *nascent ferrous carbonate* in definite doses, so that the weakest stomach can most surely assimilate the iron. Despite the fact that so much soluble iron is presented, there is no tendency to nauseate patients, for the consistence of the material of the excipient allows of gradual ingestion only. They are shown in perfect condition, the manufacturers having overcome the tendency to form a little ferrous carbonate between the surface of the capsule contents and the gelatinous envelope which their earlier samples showed. In consonance with the enterprising business activity which is a characteristic of this firm, they showed a "new departure" with the P.B. pills. In this they had put up in an elegant capsular form the different formulæ given in the B.P., claiming their entire, ready, and certain solubility. On their stand was to be found a display of well-prepared granular preparations, containing, amongst others, phenacetine, sulphonal, antifebrine, bismuth and pepsin, antipyrine, and hydrobromate of caffeine. They make a speciality of the compression of perchloride of mercury. These were shown in pellets of three strengths—No. 1, No. 2, and No. 3—one dissolved in a pint of water forming a solution of 1 in 3000, 1 in 1500, and 1 in 1000 respectively. It is needless to say that, viewed either from a pharmaceutical or medical standpoint, these pellets are not only definite, but very convenient in obstetric practice. We should say that the busy practitioner would find them invaluable. Of the other preparations we were most attracted by a concentration prepared from the bark of quillaya saponaria, which is called "equaloid quillaya sapon." A combination of ferrous iodide with the hydriodates of quinine and strychnine as a sweetened preparation, "syrup hydriod. co.," has been prepared by them for many years, and we believe is now very extensively prescribed. It appears not only a most elegant, but a most excellent and useful combination.

The Maltine Manufacturing Co. deserves a fuller notice, but space prevents. Their Maltine is an admirable extract of malted cereals, of the diastasic powers of which we have often had occasion to speak highly. Mixed with cod-liver oil, it disguises the fishy taste and smell. Maltine is also prepared in combination with lime, phosphates, Easton's syrup, phosphorus, etc., so that it is possible to obtain the nutritive and digestive properties of the malt while administering other forms of nourishment and special medicaments.

The Santha Tea Company was well patronised during the afternoon, when visitors had an opportunity of partaking of the cup that cheers, etc., made from a specially prepared extract, in which the tannin is neutralised and rendered innocuous.

Dahl's Agency.—At this stall were seen the well-known Dahl's Dyspepsia Cakes, made from the layers of various cereals, indicated in cases of constipation and indigestion. There were also shown cakes powdered, for delicate cases and for children. They also showed Larentzen's Cream and Malt Extract, prepared from the richest cream and the finest extract of malt. It is very palatable and easily digested, and forms a very good nourishing food for children. A new disinfectant, Thanelene, which combines all the qualities of the best antiseptic and disinfecting agents, is also put forth in two forms, in powder and fluid.

W. E. Sacker & Co.—At this stall there was a very large selection of hypodermic cases, hypodermic solutions, pressed pellets, tablets, etc. We were very pleased with the medicinal capsules, which were neatly and elegantly made, and which are a pleasant method of administering nauseous drugs, as copaiba, etc. Messrs. Sacker are the agents for the nutritive suppositories of Griffin, of Bath. These suppositories are made in the form of a cone, and weigh about two drachms. Each cone is equal to three ounces of peptonized beef tea. They are very carefully prepared, and will keep a reasonable time. We have found them of very great service in some critical cases. The number to be used to depend on the nature of the case, and vary from four to six a day.

Christy, Thomas, & Co., 25, Lime-street, London.—We are always sure to find at Messrs. Christy's exhibit something out of the common, as this firm makes a speciality of bringing into use from almost every clime medicinal plants, and they encourage the study of their uses. Here we have schinos, imported from the East, which is said to be stimulating, invigorating, and revivifying; Holarrhena bark, siegesbeckia, sagapeuum, burra gokeroon, jambul, etc. Apart from these drugs Messrs. Christy are showing their well-known menthol cones, chaulmoogra oil, kola chocolate, and other preparations of kola, caffeine, papaine in powder, lozenges and pills, etc. In recent numbers we have alluded to the value of the new surgical tissue Christia, and to their coated spring bougies.

Viking Food and Essence Company.—This company puts up most of their products in glass jars, and this method appears to us to possess very great advantages. The foods look inviting, and the state of a jar can be readily seen by holding it to the light. Great care is taken in the selection of foods, and also with the hermetical closing of the lids. Here we had essence of beef, beef tea jelly, meat lozenges, real turtle soup, prepared from the West India turtle, turtle consommé, etc., all of which can be recommended for the invalid in cases where the appetite is fastidious or nutriment wanted.

Burroughs, Wellcome, & Co.—Dr. Ward Cousins, Portsmouth, has entrusted to Messrs. Burroughs his new and ingenious artificial ear drum. It is a very delicate little contrivance, somewhat in the shape of a Welsh hat with a high crown. It is made of compressed cotton wool, which is saturated with some aromatic oil; and a very ingenious little forceps for introduction and extraction accompanied the box. This drum will be found of use in many cases of deafness caused by perforation of the drum. Here was a large assortment of hyperdermic cases, tabloids, triturates, various preparations of eucalyptus, terebene, strophanthus, hazeline, and a full line of specialities of the firm. A speciality was made of hazeline ointment. In the small room was shown the Kepler malt extract and Fellows' syrup of the hypophosphites, so well known for its invigorating properties. Messrs. Burroughs also showed a new system of ventilating buildings, at the same time charging them with any desired perfume. This process, we believe, is not patented; it acts well, can be readily controlled, and can be cheaply applied, especially in buildings where there is already an engine.

Allen & Hanbury's.—Messrs. Allen & Hanbury exhibited their bynin pepsine and liquid malt, byno pancreatin, byno hypophosphites, bynol, medicated lozenges, medicated pastilles; many new preparations, as their syrup of hydrodic acid, paraldehyde, phenacetin, sulphonal, salol. Their tasteless castor oil is so well known we need say very little about it.

Corbyn, Stacy & Co.—This well-known firm had an admirable display of the purest drugs, including very fine specimens of liquor cinchonæ rubra, liquor santal comp., liquor euonymin. Their new dry sparkling cocoa wine, which is free from any flavour of the drug, was very much appreciated. It is needless to say they had a number of new chemicals—antefebrin, hypnone, exalgine, etc.

Mr. G. Mellin exhibited samples of their well-known food for infants and invalids, a preparation of which, done according to Liebig's formulæ, can be well recommended. This food has a very large use. This year Mellin's exhibited vin de coca, emulsions of cod-liver oil and hypophosphites.

Messrs. G. Mason & Co.—The dietetic specialities of Messrs. Mason include essence of beef, veal, mutton, and chicken. This consists solely of the meat juices without water. Mason's concentrated beef tea contains the concentrated soluble constituents of the beef. We can strongly recommend their beef tea jelly, which can be eaten cold, and those who like a delicately-flavoured beef tea will find it in the O. K. bouillon.

C. J. Hewlett & Son.—We were able to inspect at Messrs. Hewlett's a few beautiful preparations of liquor ferri iodidi, liquor santal flav., and a mist. pepsin co. cum bismuth. They had also an excellent preparation in the form of a mist., called mist. tuss. rub. conc., which will be found very useful for dispensing purposes. Their exhibit was an exceedingly good one, consisting of all the new pharmaceutical products.

Reynolds, Branson, & Co., Leeds.—Messrs. Reynolds & Co. had a large diagram giving a synoptic table of the preparations included in the London Pharmacopœias, from nearly the earliest (1618) to the latest (1836), and in the British Pharmacopœias of 1867-1885. They had also a series of concentrated infusions, peculiarly representing the unchanged active principles of respective drugs.

Oppenheimer Bros. and Co. had a good show of their well-known liq. euonymi. et pepsin co., caulophyllin et pulsatillæ co., carnavena wine, a medicated wine containing the active principles of oats, meat, and coca.

Messrs. Seabury & Johnson had a display of pharmacopœal, medicinal, and surgical plasters, absorbent dressings, antiseptic and other surgical specialities. They also exhibited their new antiseptic germicide and preservative, "hydro-naphthol," and the various preparations therefrom for use in the practice of antiseptic surgery, and Seabury's compound sulphur candles for disinfection, etc.

Messrs. F. Newberry & Sons exhibited a collection of their sugar-coated pills, granules, and parvules. Their bromo soda, with caffein, is useful in cases of sleeplessness, in cases of over-study, brain work; and their effervescent hydro-bromate of caffeine has an important *rôle* in brain and nerve systems. Messrs. Newberry & Sons are the agents for Messrs. Warner & Co.

Woolley, James, Sons & Co., had a very large exhibit of standard medical preparations, as well as their own specialities, amongst which we may particularly mention akolethe, a solution of the sedative principles of opium, of the same strength as the official tincture—iso butyl nitris, for inhalation in cases of angina pectoris; liquor stypticus, suggested by Mr. Walter Whitehead, F.R.C.S. This is a balsamic solution of iodoform, and is used by Mr. Whitehead after the removal of the tongue to paint the floor of the mouth, and for injection in the early stages of carbuncle, bubo, etc. They had also some tannin discs, suggested by Mr. Lund, and Unna's plaster mulls.

Messrs. Carnrick & Co. exhibited, in connection with the Maltine Manufacturing Company, their beef peptonoids and soluble foods. The maltine products and compounds were exhibited in great variety.

Messrs. Loeflund & Co. showed their well-known pure hordeum malt extract, as well as combinations with lime, iron, pepsin, and hops. Their Alpine milk biscuits are well suited for children, as they contain 25 per cent. of peptonised milk substance, and 3 to 4 per cent. of phosphates. They are ready for use, only requiring the addition of boiling water. They have also a cream milk, which is prepared by a careful process of sterilisation, and which contains 10 per cent. of pure milk fat. Their Kindermilch is another infant food, claimed to be free from starch and cane sugar. Their factories are in the Bavarian Alps.

Chas. Green & Co., Tower Chambers, Moorgate, London, E.C., again had an attractive exhibit of their various preparations, which included their well-known permanent hypodermic solutions, together with a splendid assortment of hypodermic cases; corrosive sublimate (acidified) tablets for making antiseptic solutions to wash operators' hands, instruments, and other appliances, also for vaginal douche. Mr. Green explained to members the process of *upward percolation under pressure*, by which this firm make all their fluid extracts, and exhibited a working model of the percolator which is used in their laboratories. Their exhibit included beautifully-made specimens of gelatine flexible capsules, containing antifebrin, antipyrin, cascara, sandal wood oil, salol, sulphonal; Blaud's pill mass, and many other preparations which have a pharmaceutical interest.

SECTION B.

Section B. was devoted to pathological specimens, and in this Section were to be seen a number of specimens furnished by Mr. Atkinson, Dr. Barrs, Dr. Cathcart, Drs. Churton, Crocker, Drummond, T. Ward, Professors Griffith, Harris Thomas, Dr. Jacob, Mr. Jessop, Professor McGill, Dr. Thomas Morton, Dr. Bevan Rake. Dr. Bevan Rake's specimens illustrated the lesions of leprosy, and included:—1. Leprous tubercle from chin, and thickened median nerve. 2. Fingers, tubercular leprosy. 3. Fingers, tubercular leprosy. 4. Fingers, tubercular leprosy. 5. Finger, anæsthetic, leprosy, showing separation of bone. 6. Toes, anæsthetic leprosy, thickening and ulceration. 7. Toe, showing recent ulceration and old changes in nail (leprosy). 8. Anæsthetic toe (leprosy). 9. Hand, tubercles and contraction (leprosy). 10. Hand, anæsthetic leprosy, showing thickening and contraction, changes in nails, etc. 11. Toes, tubercle and ulceration (leprosy). 12. Toes, tubercle and ulceration (leprosy). 13. Leprotic kidney, showing cysts. 14. Leprotic kidney, changes and early cysts. 15. Larynx, early ulceration and thickening (leprosy). 16. Larynx, stages of ulceration and thickening (leprosy). 17. Larynx, ulceration and thickening (leprosy). 18. Larynx, old ulceration, thickening and deposit (leprosy). 19. Leprotic testis. 20. Leprotic spleen, tubercle, etc. (in glycerine jelly). 21. Ileum with Anchylostoma Duodenale attached.

The Yorkshire College had a very excellent series of specimens, arranged by Dr. Jacob, the curator, and by permission of the Council of the Royal College of Surgeons there was a choice selection of coloured portraits.

Mr. Jonathan Hutchinson also exhibited four portraits.

SECTION C.

This Section was devoted to anatomy and physiology, and the principal contributors were Professor Griffith, Dr. Oliver, Dr. Hellier, Professor Birch. Messrs. Newton and Co., London, and Messrs. Reynolds and Branson, Leeds, contributed a number of instruments used in pathological research.

Amongst the exhibits of Professor Griffith and Dr. Oliver were to be seen specimens and drawings from the Anatomical Department, most of which have been recently added to the collection. These included:—

Basin Specimens, as follows—1. Frozen vertical section of male pelvis. 2. Dissection of popliteal space. 3. Dissections of sole of foot.

Collection of Meckel's Diverticula.

Collection of Abnormal Arteries.—1. Right subclavian arising *last* from arch of aorta, and passing behind trachea and œsophagus. (Persistence of right posterior aortic root). 2. Origin of vertebral and inferior thyroid from aorta by a common trunk. 3. Abnormal renal arteries. 4. Obturator arising from deep epigastric. 5. Inferior thyroid passing behind vertebral. 6. Radial artery, represented by a large vas aberrens passing superficial to exterior tendons of thumb.

SECTION D.

INSTRUMENTS, BOOKS, ETC.

Arnold & Sons had a very large exhibition of surgical instruments for gynæcology, lithotrity, ovariotomy, etc. Amongst the most recent additions to their list are Green's new pad for fractured clavicle, Dr. Duke's new rapid uterine dilator, Foulerton's urethral injector, Sinclair's circumcision clamp, Pearse's membrane aspirator. The splints they exhibited under the name of Levis's patent metallic, possess great advantages. They are light, flexible, clean, and adaptable for every size and condition of limb. Dodd's practitioner's knife is an ingenious little instrument, as it contains six blades, with probe and director. They had a large number of Dr. Ward Cousins' inventions, but we must give a special space to a few of his contrivances.

Cousins, John Ward, M.D., Riversdale, Southsea.—Dr. Cousins, through Messrs. Reynolds and Branson, Leeds, showed a number of instruments. 1. A new evacuator for litholapaxy and other bladder operations, which has the merit of being rapid in operation, and not allowing the regurgitation of fragments. 2. A case suitable for army and navy surgeons, which deserves the application given to it by a Blackburn surgeon, of being a collection of "nice saws and modern instruments." The case consists of new surgical saws, spoons, chisels, gouges, and drills. It is a *multum in parvo*. 3. A new aural injector and evacuator. 4. A new Eustachian catheter, with hand-ball injector and evacuator.

Messrs. Down Brothers are noted makers of instruments suitable for special work. On this stall were to be seen eye instruments of the most perfect finish, laryngological models of the newest and most improved pattern, and all the armentaria suitable for every kind of special practice. Amongst the latest novelties we noticed a new osteotome, by Mr. Campbell Gowan; Basdon's chloride of ammonium inhaler; an electric light apparatus, with Kingsland's new patent accumulator. The breast pocket case suggested by Mr. Symonds, of Oxford, was a miniature portable case, and can be carried in the

breast pocket, and was an admirable specimen of neatness. Messrs. Down Brothers carried a full line of instruments suitable for general practice.

Gardner, J., Edinburgh, had a selection of useful surgical instruments.

Godfrey & Cooke.—Their patent chloride of ammonium inhaler is now recognised as one of the best, and several modifications have been made so that it can be applied to the various cavities of the ear, the nose, the eye, etc. This form of inhaler has great merits, owing to its portability. It does not contain water, another great advantage, and it can be charged with a minimum of trouble.

Lynch Brothers had a most imposing display of ether bottles, artery forceps, aspirators, bags, most improved patterns for midwifery instruments, by Barnes, etc. They also showed improved Faradaic batteries for physicians visiting; Bistouries Bodenhamer's rectal speculum; Brunton's auriscopes, which will be found very useful to medical men; laryngoscopic lamps with stands, or to fix on walls; Lawson Tait's pressure forceps, Godson's uterine dilators, Ward Cousins' tongue depressor, Teal's eye probes, *post-mortem* cases, ear syringes, enemas (Lynch's glass valves), and a variety of most forms of instruments in daily use. Messrs. Lynch and Co. also showed some silk air pillows which do not become hard, and can be carried in the pocket.

Mainchi, L., M.D., Malta, showed tablets of ophthalmology.

Pearse Ford, M.D., F.R.C.S., of 27, Alfred Place, Bradford Street, London, showed a selection of surgical instruments.

Routh, C. H. F., M.D., 52, Montague Street, London, showed a collection of directors, ecraseurs, buckle pessaries, intra-uterine pessaries, etc.

Reynolds & Branson, Leeds, had a large show of surgical instruments, dressings, etc., amongst which were Mr. Teale's sinus scoops, Mr. Hewesson's nasal dilator, Mr. A. Mayo Robson's salufer wool, a surgical dressing; also Professor Mc'Gill's salicylic silk; new iodoform dredger, trusses of various patterns, all rubber, glycerine pads, pessaries in great varieties, etc. Messrs. Reynolds and Branson also showed their well-known portable continuous current batteries, patent constant battery for lamps, motors, etc. Altogether Messrs. Reynolds and Branson are to be congratulated on their good show of instruments.

Schall, K., Electro-Medical Instrument Maker, had a splendid show of electrical instruments for illuminating the ear, eye, nose, mouth, larynx, œsophagus, stomach, rectum, bladder, urethra, and vagina. Their continuous current batteries, batteries for electrolysis, combined batteries, galvanometers and electrodes, batteries for galvanic cautery and electric light, were all most perfect instruments, each one in themselves. Space will not allow of a fuller description of them in this notice.

Shipton, J. S., M.D., Deputy-Surgeon General, A. M. D., Leeds, showed splints for gunshot and other compound fractures of the limbs.

Weiss, John & Son, London, are so well-known in the surgical instrument line, that it would be needless to say more than they had as usual a good show of the most improved surgical instruments, and the numbers of medical men at their stall showed the interest taken in their specialities.

Wood, Joseph & Co., Yorkshire, showed instruments (surgical), trusses, bandages, instruments for the treatment of deformities, spinal and other supports, all of which attracted great attention.

Dr. Churton, of Leeds, showed a method of case reporting, and Mr. B. Allsopp, *Shipley Times* Office, Saltaire, some A. B. C. medical account books.

Pentland, Young J., Edinburgh.—The manner in which Mr. Pentland produces his books calls for the highest praise. The types from which the impressions are taken are characterised by their clearness and elegancy, and the printing is done with an absence of roughness which satisfies the eye, so that the turning over the leaves of a book like that of Mr. George Berry, F.R.C.S., etc., on "Diseases of the Eye," becomes a positive pleasure to the lover of books. This is a magnificent 8vo of 678 pages, illustrated with a large series of coloured plates, from original drawings. All are excellently reproduced. Mr. Pentland had on view American and English works. We can only allude to a few. Byron Bramwell's works are well-known. They are produced in his very best style, as for instance "Diseases of the Heart and Thoracic Aorta." This is a large 8vo, of 785 pages; it has 226 wood engravings, and 68 pages of lithograph plates, exhibiting 91 figures. It is as useful a book as it is beautiful. "Diseases of the Spinal Cord" is another work worthy of distinction. The work of Dr. Allan Jameson on "Diseases of the Skin," is well-known to Edinburgh students; so are Ramsay Smith's "Illustrations of Zoology," and Sims Woodhead's "Practical Pathology and Pathological Mycology." The illustrations in both these works are excellent. Amongst the American works we noticed the first volume of Dr. Keating's "Cyclopœdia of the Diseases of Children," a fine 8vo of nearly 1000 pages, admirably printed and illustrated. There will be four volumes to complete this work. Mr. Young Pentland is the English publisher of this work. "The American System of Gynæcology and Obstetrics," four volumes, of about 900 pages each, is another enterprising work deserving of notice. There were other American works by Gross, Landis, Herwitz, Roberts, Bartholow, Louis Starr, etc. The translations introduced by Mr. Pentland are numerous, including such standard works as "A Text-book of General Botany," by Behrens; "The Refaction and Accommodation of the Eye, and their Anomalies," by Landolt; "The Parasites of Man," by Leuckhart; "The Diseases of the Ear, and their Treatment," by Hartmann, etc. Mr. Pentland has rapidly come to the front as a medical publisher; our old London houses will have to look to their laurels.

"The Provincial Medical Journal" and "Contemporary Medical Men," 10, Friar Lane, Leicester. Mr. Jessop's likeness in the August issue was much appreciated. It was an admirable representation of the popular president of the Surgical Section. Dr. Tidy's likeness in "Contemporary Medical Men" excited interest, owing to the Maybrick trial. The execution of the lithographs in this volume do great credit to the printer, Mr. Lead; they are as true to nature as art can go.

Davis, Mr. F. A., 139, Oxford Street, London. Mr. Rebman represented this house, and had an excellent assortment of some of the newest and best American works, some of which were elegantly bound. Ramsey's work on "Diseases of the Nervous System," with its beautiful plates and diagrams, was much and deservedly admired. The Annual of the Universal Medical Sciences, edited by Sajous, is a wonderful book, and the more we examine it the more we are struck with the thoroughness with which it has been done. The labour of editing such a work is Herculean. The proof-reading has been admirably done, for accuracy in a work of reference is all essential, and there are thousands of references in the annual. Another book of very great interest is the Text-book "On the Physiology of the Domestic Animals," by Robert Meade Smith, A.M., M.D., in 938 pages, with over 400 illustrations. We can only briefly allude to some of the other works, as Mear's "Practical Surgery," Massey's "Electricity in Diseases of Women," James's "American Health Resorts." The execution of these works, as regards printing, plates, and illustrations, fully sustain the credit of this house.

SECTION E.

SANITARY AND AMBULANCE APPLIANCES.

Barlow, W., Bolton, showed samples of their patent souple boots. We can recommend them for their pliability and easiness for the feet.

Boyd & Co., Belfast, showed their patent doctor's coats, now so much worn by medical men, and so useful in riding, driving, etc. It is the most comfortable coat we know of, and should be used by all country practitioners.

Billington Bros., Liverpool, showed a good assortment of spring mattresses and other hospital furniture. Their asylum bedstead was worthy of notice, as the patent woven wire mattress, specially attached to frame, avoided injury to the patient. They had also a patent system of folding-bedsteads, with spring mattress and best white canvas pillow, also folding camp bedstead, invalid's couches fitted with spring backs, mattresses composed of antiseptic pine wood wool, suitable for institutions in lieu of straw.

Bulwer, G. B., Architect, Leeds, showed patent ventilating lintel for easy admission of air into rooms.

Dixon & Son, Leeds, showed oriental shower baths, improved fire-clay sink, double lavatory (Morrison's patent), and Magnen's water filters.

Donegal Industrial Fund, The London, showed samples of sanitary hosiery and vegetable dyeing.

Gale, George, & Son, Leeds, showed patent Dominion spring mattress, combination spring bed, and the "Lawson Tait" hospital bed, all good samples of beds and mattresses.

Jacob, Ernest H., M.D., Leeds, showed a ventilating coil case, with valve for steam or hot water. The air is admitted from the outside, and passes either over the heating coils, or unheated, according to the position of the upper valve. By adjusting the valve the air can be admitted at any required temperature. The lower valve is shut only when the room is to be heated previous to occupation, and no ventilation required. The air then circulates from the room, through the coil box by the lower opening.

Wooderspoon & Co. showed a number of temperature charts, which will be found extremely useful.

Hazell, Watson, & Viney, Hatton Garden, London, owing to want of space, were placed in the Sanitary Department, and here specimens of Smith's visiting list, medical ledgers, day books, etc., were shown; they had also a collection of new medical works, and specimens of the "Illustrated Medical News." The chromo-lithographs were admirable.

Sanitary Appliances, Ambulance, etc.—In connection with the Medical Staff Corps were to be seen a number of Field Companions, medical and field fracture boxes, fitted up by Messrs. Savory and Moore. These cases left nothing to be desired in the way of equipment.

SOME FRENCH CONGRESSES.

[FROM OUR OWN CORRESPONDENT.]

WE have had a good time with our congresses, the Exhibition affording an opportunity of organising, or rather an excuse for calling together a number of enthusiasts, scientific men, bores, wind bags, and all that goes to the making of a congress. In congresses held in a foreign country, everyone can enter, if he be decently dressed, can write his name and address, and pay his contribution. Thus the English medical man of bad repute can join a French congress, the French medical man of bad repute a German or English one, etc., etc., and many men do attend congresses with objects in view outside the progress of science. I do not see, however, how we can prevent this.

There have been many congresses in which medical men could join, as, for instance—*Congress International d' Assistance Publique.* This Congress took place from July 28th to August 4th, and was opened by M. Theophile Roussel, with M. Thulié as secretary general. M. Thulié said at the opening at the opening that the Congress proposed to seek by comparison of what is done abroad, and by the help of all classes of workers for the best method of rendering public assistance. The time of the Congress was taken up with discussing many social problems affecting the well-being of humanity, and amongst which came such a problem as the organisation of medical help in the country, on which there was an interesting discussion raised by M. Theo. Roussel, and a variety of information was contributed by different countries. M. Angel Gavino (Mexico) said that there private initiative was first depended on, but that the tendency was for the State to take up the question, which it had done, so far as regards medical and surgical aid. M. Dermello Viaria (Lisbon) told us that assistance was rendered by the State, by the departments, and by private initiative, but public assistance was only obligatory for foundlings, and for the poor under certain limits. The religious took upon their shoulders a large portion of the relief. M. Bagenow (Moscow) said the organisation of medical relief dated back from the reign of Alexander II., twenty-five years. There were small communal hospitals, with fifteen to twenty beds, with district officers who had a range of work of fifteen to sixteen killometres. In the large cities there were fine hospitals, and for the insane they were organising. Moscow had now a fine asylum. Mr. Severeand (Roumania) said that the Roumanian system had been re-organised by a French military doctor, M. Divallat, and it resembled the French system. There was a new feature, in addition to the provision they had made for certain centres. There were scattered districts and scattered houses for which it was difficult to provide. They had overcome this by providing travelling physicians, who went from place to place with ambulance material, and who gave advice and dispensed medicines, and whose stipend was about 1,000 francs a month. M. Milan Vladmir Vassil (Servia), explained the organisation of his country, which was analogous to that of Roumania, but always directed by the State. M. Balavcky said that Bohemia was served by three grades of medical men—physicians attached to the civil service, district physicians, and private physicians. Each commune was obliged to have a physician, who was paid by the commune. Vaccination was compulsory, and cost 100,000 francs a year. M. Vanderlych (Moravia) said medical assistance in Moravia was precisely carried on under a law which had been refused in France. Each commune had a practitioner for the poor, and for other duties connected with civil administration. M. Alberto Costa (Argentine Republic) gave a full description adopted under this cosmopolitan Republic, and it would certainly appear from his description that this State was in as forward a condition as most of the other countries. M. Khames (Hungary) and M. Hehl (Massachussets) also spoke.

This short account of the observations of a few of the speakers will give you some idea of the scope of the discussions, and you will see how far medical men are interested in them.

The Congress of Therapeutics and Materia Medica was from the 1st to the 4th of August, and was a very successful one, and I may allude to a few of the papers. In the section devoted to therapeutics, M. Semmola, of Naples, detailed some experiments he had carried on, on the treatment of different dyscrasic maladies, and he had come to the conclusion that the exact measure of improvement was to be found in the increase in hæmoglobine in the blood. He referred particularly to the treatment of syphilis by mercury, on which he was able by the chromo-cytometric method to establish a few points. 1. Progressive syphilis not treated by mercury provokes a diminution of the hæmoglobine. 2. Animals, when given mercury, suffer also from a diminution of hæmoglobine. 3. Syphilitic patients after a course of mercury improve, the quantity of hæmoglobine became greater. Professor Semmola, by means of the hæmochromo-metric method, would measure the curative results of mercurial treatment, and it was superior to clinical examination. Professor Semmola spoke with approval of the instruments of Bizzazero, Malassey, and Von Plessets. Space will not allow me to give an account of the paper by M. Lavarx (Paris), "On the Employment of Cocaine in Affections of the Urinary Passages," and many other papers of which an abstract would be very useful. I hope to be able to transmit you a full synopsis, because therapeutics and materia medica must be particularly interesting to your readers, and I find on turning over your pages that you make a speciality of these subjects.

Another Congress—viz., that on Alcoholism was held from July 29th. Many important questions were discussed, as "The Means of Diminishing the Consumption of Alcohol," "The Responsibility of Alcoholics." For those who have the drink crave, I agree with the opinion of the delegate from London—"That total abstinence is the only safeguard." The suppression of cabarets and drinking shops appears to me to be imperatively demanded as thereby temptation is put in the way of the working man. We may have congresses and discuss this drink question *ad infinitum* without result, because the old question turns on revenue. As long as governments derive their chief income from spirit duties, and as long as the mass of the people are passive, we, as a profession, are powerless. Though we must relieve our consciences and give the results of our experience. The subject of responsibility of the alcoholic is a very important one, and was introduced by Dr. Motet. What is wanted is interdiction and internement, and here the question of the liberty of the subject comes in, and many delicate points arise. Drunkenness, especially habitual drunkenness, might be very easily suppressed by the plan put in force I believe in one country. The drunkard, on conviction, is not sent to prison. No matter what his position may be, he is set to some manual work, to clean the streets, empty the ash tubs; thus he is exposed to some personal indignity and annoyance, and at the same time he is made useful. This is not like the old stock plan. You put a man in prison for fourteen days at great expense, and you may thereby deprive the man's family of food, but by this open-air system you save the expense of his keep, and if the family be badly off, though you give a subsidy, you would still be a gainer. The reformatory influence of a good brush is very great, and I should like to see it put in practice. The habitual drunkard who wastes his own patrimony and that of others, and causes domestic unhappiness, and who neglects his children, etc., ought to be treated with a vigorous hand, extending to him our full sympathy and compassion, but at the same time having some consideration for his victims. He is really a selfish criminal, and though, unfortunately, he is often surrounded with a halo of sentiment as many criminals are.

(*To be continued.*)

Medical Miscellanea.

THE subject of our next illustration will be William Francis Ainsworth, Ph.D., F.S.A., F.R.G.S., L.R.C.S.

* * * *

His Royal Highness, the Duke of Bavaria, M.D., has just done his one thousandth cataract operation.

* * * *

We regret to announce the death on August 1st of Surgeon-General Galbraith, who had the medical charge of the troops at Cairo.

* * * *

A new wing is to be added to the Leeds Infirmary. The new erection will be in general keeping with the present building, with which there will be communication by corridors. The estimated cost will be £17,000.

The Croonian lectures, 1890, will be given by Dr. Ferrier, and those for 1891 by Professor Burdon Sanderson.

* * * *

Sir James Paget, Mr. Hutchinson, and Sir William MacCormac have been appointed members of the standing committee of the Father Damien Memorial Fund.

* * * *

Dr. Lewis A. Sayre has recently been elected an honorary member of the St. Petersburg Medical Society, which is one of the largest and most important of the Russian societies.

* * * *

On the recommendation of the Government of India Her Majesty's Government has been pleased to confer a good-service pension on Surgeon-General George Bidie, M.B., C.I.E.

* * * *

Dr. Brown-Sequard's rejuvenating fluid is said to have been tried at Indianopolis, on a decrepit old man, with marvellous effect. Ten hours after the injection the patient walked over a mile in twenty-five minutes. He declared that he felt more vigorous than he had done for twenty-five years. He read a newspaper without glasses, a thing he had not done for thirty years. It should be added that no medical authority is given for this story.

* * * *

We are sorry to have to record the death of Dr. Thomas King Chambers. He was Honorary Physician to the Prince of Wales, and a member of the General Medical Council. Dr. Chambers was a good scholar, an accomplished gentleman, and highly esteemed by all with whom he came in contact. Dr. Chambers's work on the General Medical Council was of a valuable character. He had virtually retired from practice, and his illness was of long duration.

* * * *

A case of severe articular rheumatism, which, for seven days, had been treated by the remedies usually employed in such cases without avail, is reported by Dr. H. Amon, in the *Centr. f. klin. Med.*, May 25th, 1889, as having been completely cured by six-grain hypodermic injections of antipyrin. The remedy was subsequently employed in twenty other cases with equally gratifying results. Amon usually injected the drug deeply into the muscle and in the immediate vicinity of the affected joints; a bandage with considerable pressure was then applied. In one instance he observed a slight superficial gangrene of the skin to follow the injections. Very little pain was caused by their use.

* * * *

Literary Piracy, or What?—The *New York Medical Record* made a very grave charge against us of publishing an article which had already appeared in its columns. The explanation was simple: we published it with author's permission. What shall we say now? The *New York Record* has an article in one of its August issues the MS. of which was sent to us, and which first appeared in our columns—"On a Visit to Mr. Lawson Tait." Is this piracy? Certainly not. Probably the American article was reprinted from our proof sheets, and we are very pleased that English articles should appear in American journals. We give authors three proof sheets, one of which can be sent to any foreign journal at author's discretion. "Those who live in glass houses should not throw stones."

* * * *

In an article on the resection of the sternum in the *Centralbl. f. Chirurg.*, May 25th, 1889, Dr. G. Steinheil says that the operation was first performed by Galen, and use to be most rare. Since the sub-periosteal method was introduced by Ollier it has become more frequent. Eighty-four cases were reported by Otis as having occurred during the American war, but these Steinheil does not take into consideration, as their history was incomplete. He, therefore, states that thirty-six authentic cases have been recorded. In conclusion he makes the following assertions: 1. The sternum can be successfully resected in part or in its entirety. 2. The difficulty of the operation depends upon the extent of the resection, the portion resected, the cause of the operation, and the method employed, whether sub-periosteal or not. 3. In complicated fractures, especially when resulting from gunshot wounds, the result of the resection depends upon the course of the wound. 4. Chronic inflammatory processes are the most frequent indications for resection of the sternum. The sub-periosteal method is attended by the greatest success, frequently osseous regeneration will follow. The operation is frequently performed for the removal of tumours of the sternum and mediastinum, and also to form an opening in the chest through which the larger vessels may be tied.

The first report of the Vaccination Committee has been presented to Parliament. It consisted chiefly of minutes of evidence, appendices, etc. But it will be a long time before the commission are in a position to come to any conclusion upon the evidence laid before them.

* * * *

The French Congress of Surgery will hold its fourth session in Paris from the 14th to the 20th of October. Among the subjects to be discussed are the following: "The Immediate and Remote Results of Operations for Localized Tuberculosis," "The Surgical Treatment of Peritonitis," and "The Treatment of Aneurysms of the Limbs." Business communications should be addressed to M. F. Alcan, 108, boulevard Saint-Germain, Paris; those on scientific matters may be addressed to Dr. S. Pozzi, secretary general, 10, place Vendôme, Paris.

* * * *

The Annual Temperance Breakfast in connection with the British Medical Association was held at Leeds by the invitation of Sir Edward Baines, Mr. Arthur Peace and Dr. Hannay, vice-presidents of the Temperance League. About 250 accepted their invitation. Sir Edward Baines, who is in his ninetieth year, stated that these breakfasts had been begun twenty years before the first being held at Leeds, when he was present. Short addresses were given by Dr. C. J. Hare and Norman Kell, London; Dr. Cameron, Glasgow; Dr. Ridge Enfield, and Dr. Lees. Dr. Kell stated that there were nearly 1000 practitioners who were total abstainers.

* * * *

We are very pleased to have to record that Her Majesty has been pleased to confer upon Dr. John T. Banks, at Dublin, the Knight Commandership of the Bath Civil Division. The distinction thus conferred has been warmly received by the profession generally, but particularly in Ireland, where Sir John Banks was so popular. In 1843 he was appointed one of the physicians of the Home of Industry Government Hospitals, where he is now senior physician. In 1849, he became Kings' Professor of Medicine in Trinity College; he has been President of the College of Physicians; and on the visit of the British Medical Association to Dublin he was made its president. He is Physician in Ordinary to the Queen in Ireland, and reigns Professor of Medicine in the University of Dublin. Five years ago, Dr. Banks was offered knighthood, but he declined the honour.

* * * *

Dr. Schütz, in the *Therap. Monatsheft*, May, 1889, states that, having observed the beneficial effects of compression bandages in leg ulcers, he conceived the idea of applying a similar treatment in facial lupus where, after the latter has been scraped away, large granulating surfaces are left. His method is to apply a carbolized gutta-percha plaster containing mercury to the wound, and fixes it to its place with a thick coating of collodion. This plaster should be removed every six to twenty-four hours. The change of dressings should be performed as rapidly as possible, ether being used to dissolve the collodion. After the wound is fairly closed a plain dressing should only be applied for a few days; the cicatrix may then be rubbed down with powdered marble and soap, and massage resorted to. The general health of the patient is also of great importance. A strong nutritious diet should be enforced; fresh air and gentle exercise also advised.

* * * *

The profession in London has sustained a severe loss by the death, at the age of sixty-four, of Dr. Samuel Osborne Habershon, which occurred at his residence in Brook-street on the 22nd inst. The numerous distinctions, scholarships, and gold medals, acquired by Dr. Habershon as a student at Guy's Hospital and at the London University gave early promise of his distinguished career. He took his M.D. degree at the latter University in 1851, and was elected a Fellow of the Royal College of Physicians of London in 1856, upon whose roll he afterwards figured as Lumleian Lecturer in 1876, censor in 1874 and 1875, Harveian Orator in 1883, senior censor in 1885, and vice-president in 1887. Elected assistant physician to Guy's Hospital in 1854, he became physician in 1866 and senior physician in 1873. He was one of those who felt themselves compelled to resign his post at this institution in 1880 in consequence of the action of the treasurer and governors in relation to the regrettable conflict between the medical and the nursing authorities. He delivered the Lettsomian lecture before the Medical Society of London in 1872, and in the following year was chosen as its president. He was elected president of the Metropolitan counties branch of the Brittish Medical Association in 1880. Dr. Habershon's numerous writings are well-known to the medical profession. They include:—"On Diseases of the Abdomen," "Diseases of the Stomach," "Diseases of the Liver" (Lettsomian lectures), "On the Pathology of the Pneumogastic Nerve" (Lumleian lecture). He was a frequent contributor to Guy's Hospital reports, the medical journals, and the various medical societies.

Dr. M. J. Lewis states, in the *Medical News*, that eucalyptol in doses of five grains six times daily, is useful in headaches, particularly those of a congestive character.

* * * *

The average important alterations and additions in each issue of the "Medical Directory" amount to 7,700, made up as follows: Appointments obtained or resigned, 3,200; change of address, 2,700; new members of the profession, 1,200; removals by death, 600.

* * * *

A cottage hospital is to be built at Bromsgrove, near Birmingham, and large sums have been given towards its erection. Dr. Chevasse has offered to build and furnish a male ward for six beds, to be called the Arthur Ryland Ward. Mr. Corbett, M.P., gives £500, and Lord Windsor £100.

* * * *

In Mr. Henry Irving's speech at the festival dinner to Sir Morell Mackenzie, he said "There had always been a deep sympathy between actors and doctors, but he did not know why, unless the doctors regarded the players as a little mad. Actors were on the free list of the doctors skill."

* * * *

The American Association of Obstetricians and Gynæcologists will hold its next annual meeting at the Burwell House, Cincinnati, on September 17th, 18th, and 19th, 1889. The papers and discussions will embrace subjects pertaining to obstetrics, gynæcology, and abdominal surgery.

* * * *

At Marseilles, Bordeaux, and Portiers, public exhibitions of hypnotism have been forbidden. In Belguim, Geneva, and Mecklenburg-Schwerin they are likewise forbidden. In Paris, unfortunately, unwise doctors can show off their patients, and quacks follow in their steps with unwholesome imitations.

* * * *

The subjects of the doctoral theses, recently argued at the Paris Faculty of Medicine, occupy a wide range. The first on a long list is entitled: "Facts concerning the Odorant Products of the Rose." M. Dudley Tail has his name to a thesis on "Lanolin." Three ladies have argued their theses on purely medical subjects. Among them Madame Dejerine-Klumpke née Klumpke.

* * * *

French medical journals state that a flag will be displayed at the Medical Department of the University of Paris whenever a confinement is in progress in the obstetrical ward. The colour of the flag will indicate the kind of confinement. A blue flag will indicate the confinement is simple, a yellow flag that the labour is difficult, and a green flag that an operation is necessary.

* * * *

The summer general meeting of the Irish Medical Schools and Graduates Association was held on August 14th, at the Philosophical Hall, Leeds; Dr. Fagan (Blackheath), president, in the chair. Among those present were—Drs. Macnaughton Jones, Mapother, Darkson, Halton, Professor Cumming, and Dr. Abraham (Honorary Metropolitan Secretary). Resolutions in favour of the formation of provincial branches of the association, and in reference to an official organ of publication, and a vote of thanks to the Reception Committee for the use of the hall were passed.

* * * *

The tenth International Medical Congress will be held in Berlin. The Congress will be opened on the 4th, and closed on the 9th day of August, 1890. Detailed information as to the order of proceedings will be issued after the meeting of the delegates of the German medical faculties and medical societies at Heidelberg on the 17th of September in the current year. Meanwhile, we should feel sincerely obliged if you would kindly make this communication known among your medical circles, and add at the same time our cordial invitations to the Congress. —VON BERGMANN, VIRCHOW, WALDEYER.

* * * *

The report of the Select Committee appointed to inquire into the operations of the thirtieth section of the Friendly Societies Act 1875, recommends that the age for the insurance of juveniles be extended from ten to sixteen years, but that the total amount of insurance be absolutely limited, and for the security of infant life suggest that the Registrar-General should add to the form of medical certificate of death a column demanding particulars of insurance on the life of the deceased, to be filled up by the doctor in attendance on the family. In view of the excessive prevalence of infant mortality, these provisions cannot be considered unnecessary or supererogatory.

Correspondence, Notes, and Queries.

Communications, Books, etc., should be addressed directly to the EDITOR, *"The Provincial Medical Journal," Horton House, Halifax.*

Matters of business should be addressed to the Publisher, at the Offices, 10, Friar Lane, Leicester.

We cannot undertake to return rejected MSS. unless stamps sufficient for their postage are enclosed.

We shall be glad to receive reports of Medical Vacancies, Appointments, Meetings of Societies, etc.

Papers containing passages for consideration should be marked.

Correspondents must please attest their communications with their proper name and address (not necessarily for publication).

Contributions must be written on one side only of the paper.

MSS. intended for publication to be sent in not later than the 16th of the month.

The insertion of any letter in these columns cannot be taken as necessarily indicating our adhesion to the views or statements therein expressed. The same remark applies to articles to which a name or nom-de-plume is attached.

ON AN EPIDEMIC OF BORDER-LAND FEVER AND INFLAMMATION.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—In turning out some old papers lately I came across the following correspondence. Dr. Alison's letter will be read with interest. His criticism of my use of the word "pneumonia" is just. The cases were not typical pneumonia; but they were not bronchitis in the accepted use of that word. I could not then, and cannot now, classify the cases under any orthodox name. I perfectly remember seeing men about the deck looking ill, and on examining them I should find the base of the lungs congested, and with fine crepitation. The cases in the earlier weeks were of short duration—a few days; but as the voyage progressed, and in the cold south latitudes, the cases assumed a continued fever type. There was a striking continuity in the series of cases throughout the voyage.

The experience of the voyage convinced me of the *de novo* evolution of fever, with and of changed environment; that the "specific" was not absolute in the deeper nature of fevers; that fever and inflammatory lung cases had a Form in common, and that fever may arise *de novo* out of the body, from chill.

The surgeons-superintendent of Government emigrant ships always handed over their medical journals to the colonial authorities, who sent them home to the Colonial Office in London. Some years after, wishing to work up the detail of this epidemic, I applied to the Colonial Office for my journals, but received the reply that they had been destroyed. I had not, in my voyage on the ship *Star of the South*, begun the practice of keeping a minute and systematic private medical journal. But my letter to Dr. Alison was written when the anxious experience of the voyage was very vivid to my remembrance.—Yours truly,

WILLIAM H. PEARSE, M.D.

"JANUARY 12TH, 1858,
"LONDON.

"SIR,—Please to pardon my troubling you with this communication. You will at once judge whether it be of any value in considering the causes and course of fevers, etc.

"On board the Government emigrant ship *Star of the South*, which sailed from Birkenhead in April last for Melbourne, with over 400 souls, there were from almost the commencement to the end of the voyage a great number of cases of pneumonia—I may say an *epidemic* of pneumonia.

"The passage lasted fourteen weeks.

"The cases of pneumonia became frequent about a fortnight after sailing, but yet more so after leaving the southern tropic—winter season in that hemisphere—the thermometer averaging from 45° to 54° F.

"The cases were slight. As a general description the patient would come to me complaining of 'stitch.' The expression of face dull; pulse small and rapid; an absence of well-marked inflammatory symptoms. The characteristic crepitation was always found.

"The peculiarity to which I have thought it would be worth while to draw attention was the almost epidemic character of these attacks. During week after week from six to ten such cases would happen. The patients would recover in a few days.

"In the great majority, the health being perfect in the afternoon, shivering would come on in the evening, and next morning the case would be established.

"Towards the end of the voyage the cases, instead of recovering in a few days, would pass on into well-marked fever; yet the pneumonia was in nearly all one of the first symptoms, following the shivering very early. The pneumonia and accompanying symptoms would continue without any improvement, and without becoming very severe—'hanging on,' as it were.

"There were, however, a few cases—two fatal at the end of the voyage—in which no pneumonia existed, nor any other local affection save a slight bronchitis. As a general statement, so far as I could observe, there was no difference between these first simple and the later severe cases, save in their intensity and the different period of the voyage at which they happened.

"The first fatal case of fever occurred about the end of the fifth week; no other happened in the succeeding month. A very tall and delicate young man had several attacks of epistaxis, for which he came to me. There was great subsultus tendinum, rapid and irregular pulse, and great trembling of the jaw in attempting to speak. Symptoms of fever became marked, and death in about fourteen days. Peyer's glands were found ulcerated.

"The second fatal case occurred in the twelfth week. Shivering came on a few hours after sleeping in a draught of air, and death in fourteen days. No pneumonia or other local affection. This case promised to recover after the first week, but relapsed.

"At the end of the twelfth, and during the thirteenth and fourteenth weeks, there were several cases of fever without any local symptoms.

"That which seemed worth noting was: (1) The almost epidemic pneumonia, increasing in severity towards the end of the voyage, the fever symptoms becoming then the more prominent. (2) Also towards the end, fever beginning to prevail, without local disease. (3) An apparently spontaneous case of fever, not connected with any other in time or place, and affecting probably the most delicate person on board. (4) Another case distinctly traced to a short exposure to cold. (5) Comparing different cases, there was a less uniform series of symptoms, and a different general aspect, from fever as usually seen on shore. (6) Whether one may justly, and how far, acknowledge a less specific difference of causes and conditions of the body, which result in the two maladies—fever and pneumonia. I may add that no new case arose after the people were landed.

"I believe that fever is more liable to originate (to occur) in ships whose sides are salted than in those not salted. Dr. Robertson, the health officer at Port Philip Heads, expressed this opinion.

"I must again beg you to pardon my obtruding this letter on your notice. My intention is to note the "facts of the history" of disease in an isolated community, and which might possibly be interesting in throwing light, however small, on the pathology of fevers.—I have the honour to be, sir, your obedient and obliged servant and former pupil,

"WILLIAM H. PEARSE.

"Dr. Alison."

"HERIOT ROW, EDINBURGH,
"JANUARY 19, 1858.

"SIR,—I feel much obliged by your sending me the account of the epidemic pneumonia in the people under your care, because I feel a strong interest in the question of the mode of origin or extension of various epidemics, and have always thought that a ship's company under careful medical inspection at sea is the very best of the 'organized masses of men' on whom satisfactory observations on such subjects can be made.

"I should like to transmit your letter to the secretaries of the Medico-Chirurgical Society here, who will probably make it a subject of discussion and subsequent publication; but I know that they are fully provided with matter for their next meeting, which is this week, and before another meeting, the week after next, I hope that you will favour me with some additional information, which, as I think, may increase its value decidedly.

"I should wish to know what were the whole numbers affected, and what the dates of the first and last cases? also, whether you have had any other fatal cases, and any dissections, besides those two that you mention, and in which there were the febrile symptoms with the pneumonia? and especially I should wish to know what evidence you had of the existence of pneumonia besides the crepitous rale? That rale, although in some cases very distinctly is, according to my observation, so nearly imitated in some cases by what I presume may have been capillary bronchitis only, that I should hardly trust to it in any such cases as yours unless supported by the *pneumonic sputa*, stained, not merely streaked, with blood of various colours, and the absence of respiratory murmur, and usually of movement, at *that part of the chest*. If you have not observed this, and if the crepitation which you observed was nearly alike *at both sides of the chest* and low down, I would be disposed to call these cases a peculiar form of *epidemic fever*, very generally attended with bronchitis, very much akin to what we call influenza, rather than *epidemic pneumonia*. Taking this view of them, I should think them not less instructive, although less peculiar, than if we regard them as pneumonia; but we are more certain of the accuracy of the language employed, and, as we know that almost all cases of continued fever in the temperate and cold climates, if protracted *for a certain time*, become attended with more or less of capillary bronchitis, we can understand the transition of your epidemic into the two fatal cases of simply typhoid fever which you describe.

"I should wish to know, also, whether you think any *malaria*, or any such cause in the ship, independent of living action in the human body, could have existed for the epidemic you witnessed. We have certainly had in this country epidemic pleurisy in cattle—one kind of *murrain*—and occasionally cases of typhus or typhoid fever, attended with a circumscribed peripneumony, sometimes even with pneumonia going to gangrene; but such cases in the human body are very rare, and, as far as I have seen, are complex, some more prominent form of disease acting within the chest at the time.

"I shall hope to hear from you again before the middle of February, and am, sir, your obliged and faithful servant,

"W. P. ALISON.

"P.S.—I do not know what, or how, salt is used in building ships, and shall be obliged to you for information as to that.

"W. H. Pearse, Esq."

CANADIAN DRINK STATISTICS: CORRECTION OF RETURNS OF THE DOMINION GOVERNMENT.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—Would you allow me to draw attention in your columns to certain figures contained in a Canadian Blue Book, entitled: "Report, Returns and Statistics of the Inland Revenues of the Dominion of Canada for the year ended 30th June, 1888," which seem to show that in Canada, and especially in the Province of Ontario, a great increase in the consumption of spirits has taken place in recent years? The remarkable figures referred to have been much insisted upon by the opponents of local-option, as affording conclusive evidence that the Canadian local-option law has not only signally failed to reduce the consumption of alcohol, particularly in the form of spirits. In one of the appendices (Appendix *A*) to that report there is given a tabular statement purporting to show, among other things, the average annual consumption from 1867 to 1888 inclusive, of spirits, wine and beer, per head of the population of each of the provinces of the Dominion, as well as the yearly consumption of these liquors per head of the population of the Dominion as a whole. From this appendix it appears that for the ten years immediately preceding the passing of the Canadian local-option law the average annual rate of consumption of spirits per head of the population of Ontario was 1,389 gallons; while, for that Province, for the three years 1886-7-8 it averaged 2,545 gallons yearly; and for the last two of these years it averaged 3,061 gallons yearly. There was also, it appeared, a slight increase in the consumption of beer. Now the Returns as to "Temperance Legislation, Scott Act (Canada)," moved for by Mr. M'Lagan, show that, between the date of the passing of the Scott Act and the date of the Returns, it was in the Province of Ontario and during the years 1886-7-8 that prohibition by local-option prevailed to the greatest extent. It was therefore not a little startling to local-optionists to be informed, on the authority of the Canadian Commissioners of the Inland Revenue, that in Ontario, during the years in question, the consumption of alcoholic liquors per head of the population has risen to about twice as much as it had been before the passing of the local-option law.

I felt that there must be some mistake in these Returns, and having noticed what appeared to me to be inconsistencies between certain of

the figures given in Appendix *A*, and some of those given in Appendix *B*, I wrote to the Dominion Inland Revenue Department at Ottawa, asking for an explanation of the seeming inconsistencies. Mr. E. Miall, Commisioner of Inland Revenue at Ottawa, has courteously sent me a reply in which he states that "The first issue of the Inland Revenue contains an erroneous appendix which was afterwards corrected," and he has kindly furnished me with Appendices *A* and *B* in their corrected form. Now it is very satisfactory to find, as I do from Appendix *A* as corrected, that for the years 1886-7-8 the average annual rate of consumption of spirits per head of the population of Ontario was only ·641 of a gallon, that is, it was something less than one half of the annual rate of consumption for the ten years preceding the passing of the Scott Act. But Mr. Miall warns us that "the figures as respects the individual Provinces are a little misleading, inasmuch as spirits are often entered for consumption and the duties paid thereon in one Province and thereafter carried to other provinces for consumption. The aggregate for the whole Dominion however is correct." Such being the case I shall now deal with the statistics for the Dominion as a whole; and to show the effect of the Act in reducing or increasing the consumption of Alocholic liquors in the Dominion, will now compare the quantities consumed during the ten years before the passing of the Act with the quantities consumed during the ten years after the passing of the Act, and also during the years 1886-7-8.

For the ten years before the passing of the Act the average consumption per head of the population for the Dominion as a whole was 1.471 gallon of spirits, 2.605 gallons of beer, and .194 of a gallon of wine; the whole being equivalent in alcoholic strength to 1.780 gallon of proof spirits. For the ten years after the Act was passed the consumption per head per annum was, of spirits: .909 of a gallon; of beer: 2.711 gallons; and of wine: .105 of a gallon; the whole being equivalent to 1.206 gallon of proof spirits. That is, in the ten years under the Act there has been a decrease in the consumption of alcohol of one-third. When, however, we take the last three years, we find that for 1886 the quantity of spirits consumed per head of the population of the Dominion was only .711 of a gallon of spirits, 2.839 gallons of beer, and .101 of a gallon of wine. For 1887 it was .746 of a gallon of spirits, 3.084 gallons of beer, and .095 of a gallon of wine. For 1888 it was .645 of a gallon of spirits, 3.247 gallons of beer, and .094 of a gallon of wine. The whole is equal to an average annual consumption for the three years, per head of the population, of 1.029 gallon of proof spirits. That is, under the operation of the law which is said to have greatly increased drinking, the actual consumption of alcohol has decreased from the equivalent of 1.780 gallon of proof spirits to the equivalent of 1.029 gallon of proof spirits. In other words, the quantity of alcohol consumed annually under the Scott Act, during the last three years of its operation, was equal to only four-sevenths of the amount consumed yearly for the ten years beford the Act came into operation. Now, in the face of these facts, it surely requires some considerable degree of hardihood to go on, as many people do, declaring that the Canadian local-option law has greatly increased drinking and drunkenness.

One other comparison ought to be made. As we have seen, the total consumption of alcohol in Canada, per head of the population, was, for the last three years, eqivalent to 1.029 gallon of proof spirits. But, according to Mr. Goschen's recently issued Drink Diagram the consumption per head of the population for last year, for the United Kingdom, was .93 of a gallon of spirits; 26.8 gallons of beer, and .36 of a gallon of wine, being in all equivalent to 3.7 gallons of proof spirits. If it be true, as is alleged by some people, that drunkenness prevails to an alarming extent in Canada, how comes it that, as is alleged by much the same people, drunkenness is very rare in the United Kingdom?

Yours truly, JAMES WHYTE, Secretary.

Grosvenor Chambers,
Manchester, Aug. 8th, 1889.

HISTOLOGICAL NOTE.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—To those who do much section-cutting by freezing the tissue in gum and sugar, it may be useful to learn that a mucilage of dextrine is equally efficient. I find that by taking an aqueous solution of carbolic acid (about one in forty) and dissolving therein sufficient dextrine to make a thick syrup, a medium is obtained which is superior to the time-honoured gum and sugar, in three ways: It freezes so as to give a firm support without being too hard; it keeps better than gum, in which several kinds of fungi are apt to grow; it is *much cheaper*, costing only fourpence a pound, whilst powdered gum acacia costs five shillings. Dextrine dissolves but slowly in cold water, so that a gentle heat is advisable when making the mucilage.—Yours truly,

Iron Bridge, Stourbridge, Salop. T. LAW WEBB, M.R.C.S. Eng.

A MONTHLY REVIEW OF MEDICAL SCIENCE, LITERATURE, AND BIOGRAPHY.

VOL. VIII.] OCTOBER 1, 1889. [No. 94.

Our Portrait Gallery.

WILLIAM FRANCIS AINSWORTH,

Ph.D., L.R.C.S., F.S.A., F.R.G.S.

THE subject of our illustration has long retired from the practice of either medicine or surgery, devoting himself almost entirely to scientific and literary pursuits, but always keeping himself in touch with the profession. The name of Ainsworth is a household word. Cousin of the late Harrison Ainsworth, Dr. Ainsworth inherited a share of the family genius for letters, and he is a facile writer and a successful and well-known author. It has been often made a reproach that medical men do not contribute much to general literature. We do not plead guilty to this indictment. We believe that general literature has been much enriched by the contributions of medical men, and we could quote a number of names of practitioners who have notably added to it. Like many other charges against medicine, it crumbles away when closely examined. Medical men, for instance, are accused of being indifferent to religion, and of being atheists. This charge has been often refuted, but we think in no way better than by Dr. Oliver Wendell Holmes in "Elsie Venner."

The old doctor described in the book tells a clergyman that "God opens one book to physicians that a good many of you don't know much about—the book of life. That is none of your dirty folios with black letters between pasteboard and leather, but it is printed in bright red type, and the binding of it is warm and very tender to every touch. They reverence that book as one of the Almighty's revelations. They will insist on reading to you lessons out of it, whether you call them names or not. These will always be lessons of charity." We have, however, in Dr. Ainsworth, a good example of a literary doctor, and we have pleasure for that reason in including him in our series of biographies.

Dr. Ainsworth was born in 1807; he has outlived most of those with whom he commenced his studies. His taste for travel developed in early life, and before settling down he made many excursions abroad, cultivating science, observing and educating himself, so that we are not surprised to find that in 1829 he became editor of the *Journal of Natural and Geographical Science*. On the breaking out of cholera in Sunderland in 1832, he was one of the first to repair thither in order to study the new epidemic, and he published the result of his observations in a work "On Pestilential Cholera." He was successively appointed Surgeon to the Cholera Hospital; St. George's Hospital, Hanover-square, and to the Hospitals of Westport, Ballinrobe, Claremorris, and Newport (in Ireland); whilst in that country he lectured on Geology in Dublin and Limerick. In 1835 he was appointed Surgeon and Geologist to the *Euphrates'* expedition. He published "Researches in Assyria, Babylonia, and Chaldœa" in 1838, in which year he was sent also by the Royal Geographical Society and the Society for Promoting Christian Knowledge to the Nestorian Christians in Kurdistan. His "Travels in Asia Minor, Mesopotamia, and Armenia," 1842; and "Travels in the Track of Ten Thousand Greeks," of which an analysis was also given in Bohn's edition of "Xenophon's Anabasis," were the result of the two journeys extending over a period of seven years. Mr. Ainsworth has edited "Claims of the Oriental Christians;" "Lares and Penates, or Cilicia and its Governors;" "The Euphrates Valley Route to India;" "On an Indo-European Telegraph by the Valley of the Tyris" (since carried out by the Turkish Government); "All Round the World;" "The Illustrated Universal Gazetteer;" "A Personal Narrative of the *Euphrates'* Expedition" (which has received most favourable notice from the press); "The River Karun an Opening to Commerce." Mr. Ainsworth is a member of many foreign societies. He was one of the founders of the West London Hospital, of which he is at present the treasurer and one of the trustees. For over twenty years he was a member of the Medical Board.

Original Communications.

SOME ILLUSTRATIONS OF CONSUMPTION.

By William H. Pearse, M.D. Edin.,
senior physician plymouth public dispensary.

A few years ago a family came under my notice in which the six children had died of phthisis in early man or womanhood. The father was a fine hale labourer; the mother was an uncommonly strong and hard-working woman. I could not get from the parents any history of phthisis in their ancestors, but they knew little of them. Another family, in which phthisis has appeared, has fallen under my observation, and I propose to state some facts in their history which may give a little light on the Form and pathology of this disease.

Jessie X——, æt. twenty, came to me in January, 1887. She was a general servant, and had fully and well discharged her duties during four years of such service. She had chorea when about fourteen; this had lasted one year. Her mother informs me that at fourteen she had "pleurisy and inflammation of the lungs," and, following on that, she had "fever." She had suffered boils for about four years past. The menses had commenced at fifteen; had always been regular, but scant. She was a bright, refined, and conscientious young woman; was in all respects physically well-formed and developed. She was not wasted, but plump. The infra-clavicular regions were well-clothed in fat. She applied to me in that her menses had ceased for one year. Beyond that, she made no complaint, except that she had a little cough, which, however, did not trouble her much. I found that the right infra-clavicular and right clavicular regions were a little dull on percussion; the right infra-clavicular region had dry and moist bronchial râles, and at the end of the inspiratory sound there was a short moist click. The left infra-clavicular region had capital resonance on percussion, and wheezing and cooing, and some moist râles. Though not wasted, she said that she was weak, and had felt weakness for some months. The left index finger nail had transverse sunken furrows; the eye-brows were heavy; the nose, though fairly formed, was markedly flat over the nasal bones; there was a natural sulcus between the terminal cartilages of the nose.

I sent her to her parents' home in the country, and prescribed cod-liver oil, malt extract, and quinine dissolved in muriatic acid. She rapidly developed phthisis, and died in seven weeks. I carefully avoided iron, or forcing the menses.

Her sister, Jane Anne X——, æt. twenty-five, I had known from a child. She was of splendid bodily activity and untiring energy, and exceptionally high-spirited. She had an immense amount of hair. Her teeth were a little large, regular, and sound. She had been in service, both in towns and at farms, and was always more than equal to her duties. Ten years ago she had an attack of acute pneumonia of one lung; since that attack she had been in service, sometimes at farms, at other times in towns. Her menses commenced at fifteen, and remained, during two years, full and regular. At seventeen they ceased for ten months, but returned without medical treatment, and continued regular, but scant. She had, after the pneumonia, a succession of small axillary abscesses. Two years before her last illness she was in perfect health and strength; was cook in a large establishment, and full of energy and spirit. Cough came on in the early part of 1888. She left her situation in March, returning to her parents' cottage in the country, and died in October, 1888. She was then extremely emaciated; both lungs were dull on percussion, and full of moist râles and gurgling.

Sarah Jane X——, now aged thirty-eight, was the eldest daughter. She had always lived at home up to twenty. When sixteen she had typhoid fever, and was weak for six months after. Cough, with hæmoptysis, followed at that time. Her medical man made her walk out and spend hours daily on the granite moorland. She recovered, and resumed the laborious duties of eldest daughter in her mother's large family of young children, and often working at light agricultural labour in the fields. At twenty she left her home for service, where she did a surprising amount of work as general servant, in the country—washing, dairy work, etc.

I first saw this case in October, 1876. She had cough and hæmoptysis. The left infra-clavicular region had impaired resonance on percussion, and impaired expansion; coarse inspiratory sound—almost blowing—at a spot close below the clavicle. The left sub-spinous region had impaired resonance on percussion. She was then cook in a good house with good sanitary surroundings. In a year she married, and has kept free from lung disease. Her menses are regular, but scant. Been married eleven years; has had no children. She suffers in an extreme degree from spasms, with great secretion and expulsion of wind from the stomach. She is entirely free from spasms when she takes a month's "change of air" to the moors, or with other *change* of place. The thumb, index, and ring fingers of the left hand have deep transverse ridges; but these almost wholly disappear with and after the improved general health which follows *change of air* and environment.

Emily X——, æt. twenty-two, came to me in the winter of 1888. She was then in service, but was suffering much from feeling of weakness, and distressing sense of sinking at the epigastrium. Her menses had been always regular, but scant, lasting sometimes but an hour or two. I prescribed quinine, muriatic acid, and liq. ars. hyd. after meals; malt extract with meals; and cod-liver oil at night. In a few weeks she greatly improved, and has remained well.

Augusta X——, æt. twenty, had chorea for a year when thirteen years old; her menses are regular, and full in amount; she is the youngest of a family of fifteen; has hardly strength for service; chest narrow, and breath short on any exertion.

John X——, æt. thirty-six, twelve years ago had a large fluctuating swelling on one side over the ribs, just below the angle of the scapula. It did not communicate with the pleural cavity; lasting many months, it disappeared at length under the use of cod-liver oil internally, and tinct. iodi. externally.

Of the fifteen children, five died in infancy, the eldest of such being two and a half years. A first cousin, once removed, on the mother's side, Mary D——, æt. twenty, is now under my care. A small wizened girl; very fine bones; large upper lip; all the upper incisors gone; the left dorsal region is dull on percussion, and full of moist râles; she has had cough for many years; her father's family is phthisical.

The father of the X—— family died at seventy, of old organic heart disease; he was a country mason of untiring energy and industry, modest, courageous, and of fine physique. The mother is now alive, æt. sixty. She is a

woman of exceptionally fine physique, aquiline nose, high-spirited and energetic. Her left index-finger nail is hollow. The general physique of the family is remarkable: when young, the girls have none of that soft embonpoint, and rather sluggish intellect, common in country people of the west; they are quick to learn, modest in deportment, firm in character, instantly appreciative of delicate social form; they have small bones, thin skin, but little fat, wiry and untiring muscles; the sexual is in much abeyance; small mammæ. The sons are thin, but muscular men. The girls generally have the nose thin and straight, but flat on the nasal bones like the father; the sons have more the aquiline nose of the mother. I lately made a Sunday excursion to the home of this family, to learn their family history, and to see their cottage and its environment. I had been struck that Jessie X—— had died seven weeks after her return home; and, further, I knew that Sarah Jane X——'s health had been established for good after leaving her home.

Family History.—Mrs. X——, the widow, gave me the following information: Her husband was her second cousin. Her mother died of "inflammation" at sixty-six; her father from "brain fever" at fifty-five. Her husband's father died at eighty-eight; his mother at eighty-seven. Mrs. X—— had two brothers who died in infancy; one brother died at thirty, of English cholera; one brother, supposed to be alive in America, is eighty. Mrs. X—— has one sister alive, æt. sixty-four; another sister died at twenty-five, "from nothing appertaining to consumption." Mr. X—— had two brothers; one died of typhoid at forty-five; the other at seventy. His eldest sister died at eighty; his second sister is alive, æt. eighty-one, and is active and well. I saw this old lady, who was as active and bright as most women are at sixty. His third sister died, at about forty, of a fistula; his fourth sister died at fifty, cause not known. Mrs. X——'s mother had two brothers and three sisters, the whole of them pretty healthy, and lived to old age. Her grandfather and grandmother lived to very old age. Mrs. X—— said, "my father's mother lived nearly a century; my husband's grandmother ruptured a blood-vessel, which caused death." Mrs. X—— writes me: "I remember three generations in either side who lived about ——, and none died from consumption. No such thing was ever known in the X—— family before."

The cottage, which is part of the Dutchy domain, is stone-built, of thick walls and small windows. The down stairs has one main room, about twenty feet long, by sixteen feet deep, and seven feet high[1]; slate-stone floor, the hearth and chimney large. The upper room is equally divided into two by a partition. The inner division has an open hearth and chimney; the outer is directly open to the stairs. Each room has a small window; their height is about seven feet six inches. The inner room chimney was always kept closed by a chimney-board. The house is built on the side of a steep hill, near the bottom, and on slate rock. The hill of granite rises through the slate rock to a height of 1,100 feet, the slate reaching about one-third from the bottom. The cottage faces N W; the end towards the hill has no wall for its lower two-thirds, but is formed by the bare rock. The slate rock is in well-marked layers, running upward at about an angle of 20°; thus the upper end of the house, and the floor, would constantly receive the drainage, and always be damp. The back wall of the cottage abutted also on the slate rock of the hill for its entire height and length; a trench, two feet six inches wide, however, separated the back wall from the actual rock of the hill. It is obvious that the house must have been always damp; indeed, in the winters, water would trickle out of the slate cutting which formed the higher and immediate end of the house. The granite stairs abut on this cutting, and Sarah Jane X—— informs me that during the years of her growing up the stairs were usually wet in the winter months. Immediately adjoining the lower end of the cottage was a shallow well in the slate rock. It was sunk deeper a few years ago through slate rock; and as showing the great water-bearing character of the rock, this deep well never "runs dry," but supplies the village.

We all recognize that with animals, as with plants and trees, the greatest results follow the slow and insensible influences of environment; we know that plants and animals cannot survive under certain infinitely-delicate variations of their environment: and in the general delicacy and phthisical tendency of this family we cannot exclude the slow and deleterious influences of the deficient sunshine—with its vast energies on, and correlations with life—constant dampness, and re-breathed night air.[2]

Heredity.—Although no phthisis can be traced in this family for three generations, on both sides, not the less heredity cannot be excluded, for we are the children of a thousand and one generations. Darwin says ("Animals and Plants under Domestication," 1868, vol. ii., pages 372-3): "This principle of reversion is the most wonderful of all the attributes of inheritance. It proves to us that the transmission of a character and its development, which ordinarily go together and thus escape discrimination, are distinct powers; and these powers, in some cases, are even antagonistic, for each acts alternately in successive generations. . . . What can be more wonderful than that characters, which have disappeared during scores, or hundreds, or even thousands of generations, should suddenly reappear perfectly developed. . . ." We shall be as ready to view disease, such as phthisis, as a reversion, as we are to acknowledge the principle in the instances of the appearance of limbs, peculiarities of structure, colour, and even of character.

Type.—When Jessie X——, æt. twenty—who died seven weeks after her return to her parents cottage—came to me, her physical signs were slight; there was slight dulness on percussion on the right clavicular and infra-clavicular regions. Over the same area there were dry and moist bronchial râles, and at the end of the inspiration a short moist click. The left infra-clavicular region had capital resonance on percussion, some wheezing and cooing, and some moist râles. The left side had thus a purely bronchial affection; the right lung shewed mainly bronchial type. I have records of many cases which eventually passed into

[1] Mrs. X—— objected to having her rooms measured, but my estimate is pretty exact.

[2] In the cosmic evolution we see the wondrous differentiation of the lungs, with their vast area, on the surface of which the protoplasm, or blood, is brought in contact with the molecular potentialities and energies of the atmosphere. No other actions of life are so paramount as those of the atmosphere on the blood. They are in continuity with creation, or the evolution of life. We may be sure that the correlations of expiration are as orderly and determinate against the harmonies of life, as are the molecular changes of inspiration creative and correlative to life. Chemistry and experiment now promise us a more exact knowledge, both of the energies of the atmosphere and of the composition of expired air; but here again the instinct of man has taught him a right practice prior to the actual discoveries of science. The late Dr. McCormack, of Belfast, was an apostle on the subject of consumption being caused by re-breathed air.

phthisis, in which, even for years, there existed a hovering slight bronchial condition of one or both apices. The physical signs would be purely slight bronchial. It is only from wide general conditions of function and structure that one would be able to say that such cases tended to phthisis. A large proportion of those who eventually pass to phthisis, commence by these little bronchial cooings at the apices. *How* did it happen that Jessie X——, with so slight physical signs, and not wasted, died so rapidly? I see a great number of cases, with far more physical signs, who run along in slowly or hardly progressive phthisis for years. Jessie X—— had sallow complexion, flat nose, large upper lip, furrowed nails; she suffered from weakness, though not wasted; had had chorea when a child; had amenorrhœa. All these signs and symptoms exist in thousands who do not pass into phthisis. *How* then did she? Was the cottage a hastening cause? Was the bedroom, with closed chimney, a hastening cause? Health and life depend, in individuals, on immeasurably small variations or conditions of environment. Darwin says (*op. cit.*, p. 164): "Very slight changes in the position of a plant, whether planted on a bank or at its base, sometimes makes all the difference in its producing seed." He further says (*op. cit.*, p. 145): ". . . Everyone must have observed the remarkable influence on convalescents of a change of residence, and no medical man doubts the truth of this fact. Small farmers, who hold but little land, are convinced that their cattle derive great benefit from a change of pasture." Again he says (*op. cit.*, p. 148): "Life depending on, or consisting in, an incessant play of the most complex forces, it would appear that their action is in some way stimulated by slight changes in the circumstances to which each organism is exposed." In fact, immeasurably delicate changes in environment may be restorative or destructive to life. The function of respiration, filling so great a part of animal life, cannot but, in its products, hold most complex wastes and poisons; the vast lung tract has evolved, and survived, and exists, in part, in and with, the conditions of waste, orderly *débris*, and poisons to be carried off. Jessie X—— might well not survive in the lethal gases and volatile poisons of her chamber. Jane Anne X—— succumbed in the same chamber. Sarah Jane X—— left the cottage at twenty, when in early phthisis, and has always lived since with the best hygienic surroundings; her home, of late years, has been a large house on a hill, with ventilated staircase, and for many years she has never closed her room door at night.[3]

During many years I have made notes of every case of phthisis and prephthisis which has presented. I have tabulated them under different headings as representing peculiarities of structure and function. Having published abstracts of these notes,[4] I do not propose to summarise them now, but to refer to some points only. This phthisical family exhibited *atavism* and reversion, both in function and structure. In function, Jessie, Jane Anne, Emily, and Sarah Jane, all had scant menses or complete amenorrhœa. Emily and Sarah Jane, suffered much from sinking at the epigastrium and spasms; also, though muscularly strong, they had much feeling of weakness. These symptoms, which exist in them over periods of years, indicate a deficient vital energy of protoplasm. It is the greatest error to view the amenorrhœa as mainly dependent on conditions of the ovaries, etc.; or to view the epigastric sinking as mainly dependent on nerve or other organ located there; they are symptoms involving the ultimate nature, modes, and energy of the entire protoplasm and its differentiations. The same—nearly—conditions of protoplasm and its energy, which lead to feeling of epigastric sinking in Emily and Sarah Jane, are those which have resulted in fatal phthisis in Jessie and Jane Anne. Then, as to *atavism* in structure, the mother has her left index-finger nail hollow; Emily, Jane Anne, and Sarah Jane have transverse furrows across their nails. I have often observed, that in families where phthisis has prevailed in some members of the family, that other members have transverse ridges on their nails. I have often rightly guessed phthisis in cases, from a glance at the patient's unduly large cold hands: few symptoms are more important, in those who tend to phthisis, than that of cold feet at night. Jessie X—— had flatness of the nasal bones. I cannot doubt that there is a marked correlation between phthisis and a somewhat large formation of the terminal cartilages of the nose, with a want of symmetry between the two sides, and stillness of the alæ nasi. I have very frequently noticed, that in phthisical families, the two upper lateral incisors are small, and even conical in other members of the same families. When we see disturbed function, such as amenorrhœa, indigestion, weakness, coldness, extending, more or less, over years; and, further, when we remember, that these disturbed functions involve the deepest parts of the organic evolution, *e.g.*, the sexual function, the animal heat, etc.; and yet, further, when we see that these disturbed functions correlate with peculiarities of structure, even of the bone system, we shall conclude that phthisis is, in the widest sense, a general disease, and that the lung mischief is a sequelæ and minor part of the complex series. In the whole range of the phenomena, physiological and pathological continuity are revealed to our view.

Treatment.—One of my strongest therapeutic convictions is, that I have seen a great number of young people who had symptoms of præphthisis, and even slight physical signs of phthisis, get well from a month or two's change of air. What Darwin says on the vast power for good, on plants and animals—even determining their sterility or fecundity—of slight changes of environment, is equally true of man. Young people, who have been long failing in the climate of South Devon, will be quite restored by a month or two's stay on Dartmoor, or in the south-eastern counties, etc. In the cosmic evolution, science has not yet recognised the potentialities, correlations, and essential partship of the atmosphere to protoplasm, and to its health and energies; but a right practice, based on human experience, often precedes its scientific explanation. I have been forced to conclude that it is often right to yield to the instincts and fancies of patients as to their diet. Hundreds of præphthisical and phthisical patients have told me of their craving for onions; they also long for

[3] In India, bedroom doors are often not closed. A screen—parda—of cloth hangs at the door-place. It is often so arranged as neither to reach the top or bottom of the door space. In the West Indies, the partitions of bedrooms, etc., do not reach the ceilings. Refined ladies and girls are not alarmed at these freer arrangements; but in England, warmth is essential. I often advise people to ventilate their staircases at night, by opening one or more windows in it a few inches; the bedroom doors can be made secure by the chain fastener on the inside. Thus the bedroom doors are open three or four inches all night to the pure air of the staircase; the regulators of the bedroom grates should, of course, always be open. A very pure air in bedrooms can be attained in this way. One cannot lay too much stress on this slow, but all-powerful, influence of the slighest causes, both toward health and toward disease.

[4] *Medical Times and Gazette*, 1882; *Medical Press and Circular*, 1884.

vinegar, salt meat, salt fish, dutch cheese, etc. I suspect that the waning and feeble energy of protoplasm gets an access of molecular energy from the different modes of the molecular motions of the varied aromatic groups in the onion. The distaste for fats and fresh meat, and the liking for salted foods, though not yet explicable, point toward the method of the pathology of phthisis. My usual prescription is quinine and muriatic acid. It is rare for the patients to say other but that they are much benefited. In many hundreds of cases I have combined arsenic with the above, and I have never yet seen evil from its use.

Recurring to the X—— family, it was seen that scant menses and complete amenorrhœa existed in different cases. I should strictly avoid giving iron in such cases with a view to restore the menstrual function. I should view the amenorrhœa as a result of the most general conditions—of the most fundamental lack of energy in protoplasm—and should seek by the most ordinary and gentle means to restore the general health and vigour by change of air, change of food, new scenes, malt extract, cod-liver oil, etc. I see a great number of the poorer classes in phthisis, who remain much in the same condition for years even. They are forced to go out of doors a good deal, and to take exercise, in the care of their families. They get on a great deal better than do the richer classes: in other words, they survive because they live in contact with the energies and conditions of the evolution of protoplasm —sunlight, air, rain, and the different modes of energy in constant action in the atmosphere. To pour in iron in these cases of scant menses and amenorrhœa, and thus to disturb the delicate equipoise of the complex correlations of their protoplasm seems to me to be a most hazardous and unwise practice. One may force the menstrual function, but hasten the death of the individual. The great master, Trousseau, cautions us against the use of iron in such cases. About fifteen years ago a young woman of twenty-one, of beautiful features and build, came under my care for amenorrhœa and chronic enlargement of the glands of the neck. I ventured on iron. I fear that I thus disturbed the habituated and harmonious correlations of her protoplasm. She developed rapid phthisis of both lungs, and died. Bowing before Trousseau, and following my own deductions from the cosmic breadth and infinite delicacy of the correlations and harmonies of process which exist in protoplasm, and constitute health, I have, since that fatal case, shunned iron in all cases where a suspicion of future phthisis could be entertained. I lately, however, became a backslider under temptation, and I fear with calamitous results. On October 13th, 1888, F. Z—— female, æt. twenty, came under my care. She had never menstruated. I found that she had been under medical treatment by another practitioner, who viewed her case as "never menstruated; palpitation; anæmia; giddiness." He prescribed:

℞ Tinct. ferr. mur. ..... ℥ ½
Tinct. nucis. vom. ..... ʒ ij.
Spirit æther chl. ..... ʒ ij.
Tinct. digitalis ..... ʒ ij.
Quin. sulph. ..... gr. xij.
Aq. ..... ℥ xij.
℔ A tablespoonful three times a day.
Pil. aloes c. ferr., gr. v. every morning.

I thought that I might possibly be cherishing a "fad" in my fear of iron, and therefore continued the treatment, omitting the digitalis from the mixture. I ordered her, in addition, half an ounce of cod-liver oil at night. I continued such modified treatment from October 13th, 1888, to the end of January, 1889. I lost sight of her then until the 22nd of March, when I resumed the same treatment. She was a plump, well-nourished girl, of good height and build. Her face was somewhat pale, and yet with some colour, and of a waxy type. The teeth were good and sound; the nose was well chiselled; the alæ nasi still; the external organs of generation, vagina, and uterus, were normal; the lungs were perfectly sound; the infra-clavicular regions and thorax well-developed.

On April 10th she spoke of having a slight cough. She was not wasted—on the contrary, was plump, as healthy young girls of that age should be. I found that the left infra-clavicular region had distinct crepitation, but no recognisable dulness on percussion. I now suspended the iron, and prescribed:

Quinine sulph. ..... gr. xx.
Acid. muriat. dil. ..... ʒ v.
Infus. quassiæ ad. ..... ℥ x.
℔ 20 doses. One dose three times a day.

The cod-liver oil was continued.

On May 30th, the left infra-clavicular region had not equal resonance on percussion to the right, but it was good; the breath-sounds soft, but with some sub-crepitant râle at end of inspiratory sound.

July 17th.—The left infra-clavicular region has harsh inspiratory sound, and sub-crepitant moist râles; also it has impaired resonance on percussion. The amenorrhœa remains complete. Phthisis has evolved, and is distinctly developing in the left lung. She is not wasted—on the contrary, is fully plump.

I do not assert that the iron upset the harmony of the correlations of this girls' protoplasm, and led to the evolution of phthisis; but I do feel that it was unscientific on my part, where the equipoise of vital process was so delicate and hovering, to disturb its correlations, except by the most gentle and gradual application of the tonic regimen—that is, of those energies which are parts of, or the media of, the evolution and sustentation of life—viz., sunshine, atmospheric exposure, exercise, change of environment, etc. For months I in vain urged this young woman to leave Plymouth for a month or two, and thus to apply the greatest of all restoratives—viz., change of air.

In the nebular condensation the atmosphere remains in that molecular condition, and with those energies, in and of which—in part—protoplasm has evolved and is evolving. Creation is still in process, in continuity with the Forms and laws of the past. The atmosphere is pervaded with cosmic energies; it is a sphere of infinite activities and energies—heat, light, electricity, and the vast chemical molecular energies, etc. The vast power which change of air has over protoplasm is probably the result of the fitness of the altered physical correlations contained in such change to the capacity for receptivity of the vito-chemical modes of protoplasm. As before remarked, protoplasm and the organic have evolved very much in and of the energies of the atmosphere. The varied conditions and changes of the energies of the atmosphere have therefore a natural fitness to and harmony with the vito-chemical molecular receptivities of protoplasm. But whatever be the profounder and more exact science of change of air, it is a continually recurring experience here that young people, hovering toward phthisis, are permanently benefited by carrying out the practice.

In this scattered paper I hope that I have so far viewed phthisis in just relation to wider views of biology and vito-physics, and in harmony with the deductive Forms of Continuity and Evolution.

ON THE REMOVAL OF RENAL CALCULI BY TOXIC DOSES OF BELLADONNA.

By Dr. W. Murray,
NEWCASTLE-ON-TYNE.

The treatment of renal affections by belladonna has been accepted by the profession for many years, and the efficacy of the drug in relieving renal pain is well established. The pain produced by renal calculi and renal colic is more effectively relieved by belladonna than by any other drug, opium not excepted—at least that is my experience. I was led to infer that something more than mere relief of pain might be expected, by considering the analogous condition of bowel obstruction, in which belladonna has proved so marvellously successful, and the essential point of this treatment consists in following out the analogy between the two cases. In cases of bowel obstruction, we push the treatment far beyond the mere anodyne effects of the drug, until the obstruction gives way. In cases of renal colic we have been content when the agony has subsided. I contend that we have erred in thus stopping short of more decided results; and that if the drug be administered sufficiently long, and in large enough doses, the entire removal of the calculus—first from the pelvis of the kidneys to the bladder, and then from the bladder *per* urethram—often follows.

I will not attempt to theorise on the exact physiological process by which the above results are brought about, either in the case of the bowel or in the case of the renal passage; it seems, however, as if the drug combined in itself the power to relieve spasmodic contraction on the one hand, and produce peristaltic action on the other. Perhaps someone more fully acquainted with physiological therapeutics will enlighten us on this point.

I must, however, proceed to substantiate the above views by quoting some cases in which such striking results were obtained, as to establish the link of causation between the administration of the drug and the removal of the calculus. Let me quote three cases in point:—

Mrs. E—— had suffered for several months from repeated attacks of renal colic. During the last of these attacks I was called in, and found her in the agony of a severe attack. Belladonna was administered until decided toxical effects were produced, and the patient was relieved of her sufferings as soon as the drug began to show its physiological action on the eye and throat. It was then pushed until she was fully under its influence, and in a few hours the stone passed into the utensil with the usual satisfactory click—a lithicacid calculus—as large as a small almond.

The next case was that of a young engineer, who had suffered long and severely from renal pain, with occasional attacks of true renal colic. He had been treated by an experienced practitioner without much relief. I advised the administration of forty drops of tincture of belladonna, to be repeated every hour, or every two hours, until dilatation of the pupil, dryness of the throat, and delirium were produced. This treatment was commenced in the afternoon, and during the night following he passed a calculus as large as a bean. It is to be noted that the treatment gave speedy relief of pain, but not content with this, the effect of the drug was kept up so as to ensure the passage of the stone.

The third case was that of a youth, who suffered so severely from renal pain, that it was determined at a consultation of the staff of the Royal Infirmary at Newcastle, to remove the calculus by operation. Before consenting to the operation, his parents brought him to me; I suggested the belladonna treatment, promising to send him to the hospital again if it failed. In this case twenty drops of tincture of belladonna were given at intervals of an hour, and at the end of four or five hours he passed a round and rough calculus, composed of urates; and I was able to send the boy to the hospital to present the stone to Mr. Page, from whom I received liberal congratulations.

These cases I maintain are sufficiently striking to arrest our attention, and tend to establish the fact that belladonna relieves the pain of renal colic, and by its peculiar action on the muscular fibres of the urinary passages, remove the stone.

In the present state of pharmacology we cannot say what its precise mode of action may be. It may act by simply paralysing the circular muscular fibres of these canals, thus allowing the stone to be washed out by the urine; or while paralysing the circular fibres it may stimulate the longitudinal fibres. The special point to be remembered is that we are to push the drug to its toxical stage, and keep up its action after the pain has been relieved, until a fair time has been allowed for the expulsion of the stone. We may begin with a forty-drop dose of the tincture, and repeat it every two hours, increasing or diminishing the dose according to its effect on the patient.

NEUROTIC GANGRENE (?) SIMULATING RAYNAUD'S DISEASE.

By W. Alexander, M.D., Brigade-Surgeon.

It is difficult to arrive at a satisfactory diagnosis in some, indeed in many affections. The case from which the following notes were taken was one of these, and I found it impossible to say definitely whether it was one of purpura or a case of Raynaud's disease, as it partook of the nature of each, but was in some respects different from either. The purpuric-like spots, the hæmorrhage from the bowels, the sloughs on the buttocks, pointed somewhat to the former; but the history of the case, previous good health, hygienic surroundings, and good dietetic arrangements, are strongly against that theory. On the other hand, the peripheral character of the lesions, the pre-existence of burning pains, and other neurosis, and the undoubted gangrene, point to some form of Reynaud's disease.

At the Glasgow meeting of the British Medical Association, Dr. Affleck brought forward two cases, which were afterwards published in the *British Medical Journal*, and the striking similarity in some of the symptoms induced me to show the boy to Dr. Affleck, with a view of getting the benefit of his experience as to diagnosis. I am indebted to him for his kind courtesy.

One thing struck me as common to the three cases, undoubtedly so in two, and presumably in the third, which pointed to a possible common cause—viz., the habit of eating sweetmeats.

J. H., æt. ten, was an exceptionally healthy and sturdy boy till the commencement of present illness, lived in comfortable quarters, with hygienic conditions good, and was fed regularly with good wholesome food. Parents healthy, but mother suffered severely from rheumatic fever some years ago.

April 6th.—I was called in to see him, and found his lower extremities covered with patches of various sizes, of a bright red colour, circular in form, and not removable by pressure. Tongue thickly coated, pulse very rapid, temp. 101. Prescribed calomel, to be followed by ol. ricine and other treatment.

April 11th.—Spots gradually fading away from legs, but painful swellings have been occurring in various parts—first right elbow, then left, the swellings extending up course of large vessels. The outer side of right thigh was also affected. These swellings are characterised by burning heat and redness. The scrotum and right eyelid have also been affected with considerable discoloration. These painful swellings are evanescent, coming suddenly with greater pain and constitutional disturbance, and subsiding rapidly when there is no hæmorrhagic effusion. Prescribed calomel. Bowels constipated and tongue dry.

April 12th.—Found the back of right hand much swollen and discoloured, the left eyelid in a similar condition. Pupils of both eyes much dilated and insensible to light. Urine scanty and turbid, but no albumen. Prescribed ext. ergot liq.

April 13th.—Back of hand much swollen and very dark. Penis also similarly affected. Treatment, tinct. ferri perchlor. and ext. ergotæ.

April 14th.—Several fresh shots of petechiæ on lower extremities and buttocks. Back of hand hard and black, with large bullæ. Several swellings answering to the description of erythema nodosurra have appeared on forehead and legs. A patch on each buttock, with dark centre.

April 15th.—Forearm and right elbow much swollen, and purple; pulse fresh, temp. normal. Bowels regulated as required.

April 17th.—Left eyelid going to slough. To-day considerable amount of passive hæmorrhage from bowels, which continued for several days.

April 20th.—Condition improved, but several sloughs are separating from left eyelid, back of right hand and penis.

April 24th.—No further hæmorrhage; tongue, which has been foul and parched is clearing, except at the tip. Patches on buttocks have separated and give trouble on account of their position. Treatment, iron, quinine, and ergot.

May 3rd.—General condition improving; large sphacelative surface on back of hand still in position, being bound down by the vessels and sheaths of tendons, the others coming away.

After this date he gradually improved. The large slough on the back of the hand came away, leaving the tendons exposed, all superficial vessels and nerves having been destroyed, the lower portion of skin of penis also separated, and the slough from left eyelid, but all healed without trouble.

May 18th.—After being about for some days, the boy developed a swollen and painful condition of scrotum; right ankle also became swollen and discoloured and hot, whilst the anterior portion and toes were very cold. There is apparently an impediment to the circulation in lower extremities.

After remaining in bed a few days, the condition passed away, and the boy gradually rejoined his companions and continued his pursuits and pleasures; but at the date of writing there is still a large unhealed patch on the back of the hand, due, no doubt, to the working of the tendons, which lie embedded in cicatricial products, but otherwise the boy is in good health.

In the case under observation the boy was freely provided with pocket money, all of which he spent in sweetmeats; and I am inclined to think that possibly in these the cause of this obscure affection may be found. Throughout I considered the *fouset origo mali* a central necrosis.

THE USE OF ANTIPYRIN IN THE TREATMENT OF SEA-SICKNESS.

By George G. Parsons, L.R.C.P. Lond., M.R.C.S., L.S.A., surgeon, ocean s.s. co.'s service.

Although sea-sickness is usually a trivial affection, yet when long continued, or when occurring in debilitated subjects, it may occasion dangerous exhaustion. It may also be followed by an attack of *delirium tremens* when occurring in persons of intemperate habits. The effectual treatment of sea-sickness is a matter therefore of some importance. The drugs which have been chiefly recommended for this purpose include the bromides, bismuth, chloral, cocaine, nitrite of amyl, etc. After an extended trial I have found them all more or less ineffectual. Of late I have employed antipyrin in the prophylaxis, and treatment of sea-sickness with considerable success. Of a series of twenty cases so treated, twelve entirely escaped sickness, while with the remainder the attack was markedly reduced in intensity, and shortened in duration as compared with former experiences. My plan is to administer five grains of antipyrin, freshly dissolved in a wine glass full of water at the time of embarking, and to repeat the dose in four hours. As a rule three doses at most are required. In these severe cases where nothing can be retained in the stomach, the antipyrin may be administered hypodermically, and in such cases the application of a small blister or mustard leaf over the epigastrium is usually of marked benefit.

ON THE APPLICATION OF ANÆSTHETICS IN NATURAL LABOUR.[1]

By M. Charpentier, M.D., Paris,

(*Continued from p.* 404.)

Campbell and Dutertre admit an action almost analogous.

1. *Initial and General Relief*—characterised by a slight effacement of self, and the production of physical and moral calm, by the diminution of circum-uterine or parapelvien pain. The true pains seem to concentrate in the uterus. The contractions are still painfully felt. The pulse is calm, the respiration regular; the woman understands and obeys the voice, but she has a sensation of *bien-etre*, which consoles and sustains her.

2. If the inhalations be continued, a period of complete analgesia supervenes, of semi-insensibility, characterised by weakness of pains. The parturient feels less, and a certain diminution in the intensity and frequency of the contractions is produced.

3. *Period of Complete Analgesia.*—The pain completely disappears. It is to this degree that obstetrical anæsthesia should be pushed; a few more inhalations, and we reach true narcosis. If one may rely on individual experience, this is what I have observed.

(1) Chloroform given in small doses produces incontestably what Campbell calls a period of initial relief—that is to say, a physical and moral state of calm.

(2) Pushed to a more advanced degree and for a longer time, chloroform, in the majority of cases, diminishes uterine pain; the patient feels less; intelligence is partly preserved, with other well known symptoms of ease.

(3) As regards the period of total analgesia, we have never observed that the patient was completely anæsthetised.

(4) In some cases, whatever the form of administration or

[1] A paper read at Obstetrical and Gynæcological Society, Paris, May 22nd, 1889, and published in the Bulletins of the Society.

dose, chloroform not only does not soothe, but brings on such over-excitement that we are obliged to give it up.

(5) In other cases chloroform appeared to us to weaken in a very decided manner the uterine contractility, and thus to determine more or less serious hæmorrhage after the labour.

(6) Its action on the infant has been *nil.*

(7) Chloroform administered during period of expulsion induces a certain amount of relief; but its action on contraction of the abdominal muscles, and on the resistance of the perinæum, appears to be less manifest than is generally admitted. The sensation of pain is not completely abolished; the contractions are frequent.

Indications.—We believe that in practice chloroform will be found of a great service, without wishing to apply it in all natural labours. Our *role* is above all to diminish the sufferings of our patients. If the woman to whom we are summoned feels relieved, either as a single effect of imagination, as some authors suggest, or through the action of the chloroform, the question is settled. I do not propose chloroform for every natural labour, except for certain indications, which I shall pass in review; but if the patient demands it, I believe that we have no right to refuse her a medicine which gives her actual relief.

Special Indications.—It is especially indicated in two cases. (1) In primiparæ, in certain nervous women whom pain excites to a high degree, in whom the painful manifestations are accompanied by excessive agitation, which may run into delirium; in those whom labour is prolonged, bringing on fatigue, which may not be without danger.

(2) When there is spasm, contraction, spastic rigidity of the neck or body of the uterus. These are the true indications for chloroform, and to administer chloroformic inhalations under these conditions is good practice. Besides the calm induced by the anæsthetic, these spasms—and contractions almost tetanic—yield rapidly; the labour takes a regular course, and promptly terminates, to the great benefit of mother and child.

Contra-Indications. — When the labour is normal and regular, the patient multiparous, the pains moderate, we may resist the importunity of the patient, and seek to gain time by insisting on the disadvantages of the agent. We reject it absolutely in all cases of hæmorrhage (placenta prævia), considerable weakness, in affections, of the circulatory and respiratory organs, of the brain, in alcoholism, etc. If manual or instrumental intervention be necessary, we use chloroform, but not in obstetrical doses. We want *true surgical nerosis,* and I obtain it.

The Time of Application.—Obstetrical anæsthesia finds its employment during the *period of dilatation.* At this time the reflexes are generally most intense; the agitation is greater, and the pains are more severely felt by the patients. It is then that chloroform gives most relief, producing, as Campbell points out, a state of well-being. There is absolute repose in the interval of the contractions, and disappearance of the general feeling of pain.

During the Period of Expulsion.—The woman requires to preserve the integrity of her will to aid uterine effort by the action of the abdominal muscles. Now if we continue the chloroform up to a certain time, even in small doses, we rapidly pass anæsthesia, and produce complete analgesia with absolute loss of consciousness. It is better at this period, we think, to have recourse to local anæsthetics which have a real value. The most pusillaminous woman takes note of the progress of her labour; she gains fresh courage; and numbers of times we have seen women who had demanded chloroform during the period of dilatation reject it during the period of expulsion.

Accidents due to Obstetrical Anæsthesia.—If obstetrical anæsthesia offers some real advantages, it is not always without its inconveniences. It is reproached with provoking nausea, vomiting, cephalalgia, various nervous complications, and with predisposing to puerperal accidents. Some of the former symptoms may depend on chloroform, but they are not serious. To attribute puerperal complications to chloroform, however, is a gross error. There are a number of other complications which have a more real connection with chloroform.

(1) *Hæmorrhage.*—Some authors accuse chloroform of producing hæmorrhage. That may be true when we push it to complete narcosis, and I have seen examples of it; but it is not true of pure and simple obstetrical anæsthesia, since it leaves uterine contractility in all its integrity.

(2) *Eclampsia.*—Chloroform cannot be incriminated for this condition, as it is one of the best methods of treatment.

(3) *Puerperal Mania.*—Puerperal mania occurs in subjects predisposed to it by heredity. Labour is only a determining cause, by the nervous excitement which it produces; and chloroform, by diminishing nervous excitement, is much more likely to prevent than produce puerperal mania.

(4) *Cardiac Syncope. Respiratory Syncope. Sudden Death.* Dutertre, who has collected all the cases of death attributed to chloroform, cites forty, borrowed from different authors. Out of this forty he eliminates thirteen in which death might be attributed to other causes. There still remain twenty-seven deaths absolutely attributable to chloroform. But in studying them we see that the women were suffering from cardiac or respiratory affections, or were alcoholised, and that the chloroform was pushed beyond the obstetrical dose. We may say that these accidents are comparatively rare, but in view of them we must take precautions against their occurrence.

Alcoholic Ebriety, Transient Delirium.—A few months ago I observed a curious case. A young woman, nineteen years of age, for a quarter of an hour was given chloroform which was admirably borne, and which was hardly pushed even to complete loss of consciousness. She woke up happy and gay and calm, in full possession of intelligence, and was able to talk about what happened to her. Two hours afterwards she was taken with delirium, the delirium of joy, during which the following words were continually repeated. "What happiness we must announce the good news." There was no derangement of the stomach, no rise of temperature; there was a slight rise of the pulse. This state lasted three hours. The delirium, which we can only attribute to chloroform ebriety, disappeared without the patient being conscious of it, and without any bad after-effects. I may add that this patient subsequently took chloroform up to complete surgical anæsthesia without any complication. It is generally admitted that women in labour enjoy a certain immunity as regards chloroform, and many theories have been suggested to account for it.

Chloroform and the Infant.—If it be true that chloroform penetrates by endosmosis through the placenta into the fœtal circulation, it is rarely found even in very small quantity. It exercises only a very slight influence on the fœtal heart; it does not cause the death of the fœtus, nor even jaundice of the newly born.

Mode of administration dosage.—The first condition is to employ chloroform chemically pure.

(*To be continued.*)

TREATMENT OF UTERINE CANCER.[1]

By Thos. More Madden, M.D., F.R.C.S. Ed.,

OBSTETRIC PHYSICIAN MATER MISERICORDIA HOSPITAL, DUBLIN; EXAMINER IN MIDWIFERY CONJOINT EXAMINATION BOARD; EX-PRESIDENT OF THE OBSTETRIC SECTION OF THE BRITISH MEDICAL ASSOCIATION, AND THE ROYAL ACADEMY OF MEDICINE; FORMERLY VICE-PRESIDENT BRITISH GYNÆCOLOGICAL SOCIETY, ETC., ETC.

In view of the rapidly increasing prevalence of cancer in these countries within the past few years, the treatment of one of the most frequent forms of this malady is deserving of re-discussion at this time. The actuality of that increase is unfortunately proved by the last published decennial reports of the Registrar General for England and Ireland, from which we learn that in the eleven years, 1877-87, the annual death-rate from cancer in England and Wales, among persons aged upwards of twenty-five years, was 1,186 per million; and the rate increased steadily year by year from 1,079 in 1877 to 1,331 in 1887. In Ireland, on the other hand, the mean annual rate in the same eleven years at the same ages was 828 per million; and the rates in the several years fluctuated more than they did in England, but ranged between 741 in 1880 and 935 in 1887.

In dealing with a disease so intractable and ultimately fatal in its course as cancer, it is, I think, the duty of every physician who has sufficient experience of any method of treatment still *sub judice* to publish as fully as possible the results of his practice, and the grounds on which it has been adopted, for the judgment of his professional brethren, even if the former should be deemed unsatisfactory, or the latter be found trite. Hence, having elsewhere discussed this subject at some length, I now venture to submit for your consideration a few observations borne out by my more recent clinical experience in the gynæcological wards of the Mater Misericordiæ Hospital, where a large number of cases of uterine cancer have come under my observation. In the great majority of these, the disease originated in the cervix, and in many it remained localised therein for a considerable period, and was arrested by the amputation of the affected part of the uterus. I therefore desire to urge the advantages of timely removal of the cervix in all such cases, as contrasted with the results of the subsequent extirpation of the entire uterus, whether by vaginal or abdominal methods.

The results of the latter operation, as may be gathered from the subsequent observations, are hardly calculated to favour their general adoption, even in cases so hopeless as those in which they are commonly resorted to. Another alternative to either of these operations has been recently suggested—namely, the application of a powerful interrupted voltaic current, which, acting apparently as a powerful thermo-cautery or escharotic on the specific malignant elements—whether germ cells or microbes—in the cancer infiltrated cells, may therefore, as I think, be regarded as an improved modification of the older escharotic treatment long since advocated—chloride of zinc, arrows, and other cautics formerly advocated being now replaced by the more potent galvano-cautery, directly applied to the diseased part in the manner recommended by Dr. Parsons, of the Chelsea Hospital for Women, in the *British Medical Journal*, April 24th, 1889. The effects in such cases, if produced by the action of the strong electric current—as judged from Dr. Parsons' experience of its use in four cases of cancer, in one of which the disease was uterine, and the cervix almost completely destroyed—"consists," he says, of a cessation of a growth, gradual disappearance of pain, some shrinking and hardening of the tumour and enlarged glands, followed by improved nutrition and better state of the general health. The growth, as a whole, does not disappear, but remains as an inert mass, composed in all probability of a fibrous tissue alone. Before treating these cases, I felt almost sure that this would be the case, because I had found by a number of experiments, detailed in the paper before referred to, and also from treating a large pelvic fibroma by galvano-puncture in 1887, that neither could electricity decompose the fibrous tissue of new growths (whatever it might do with cicatricial tissue), nor could the system cause its absorption after it had been rendered inert. However, it will always be open to patients to have the remains of the growth removed subsequently by the knife. The advantages claimed for this method of treatment are as follows: (1) "There is no destruction to the normal tissues of the body; and if recurrence should at any time occur, its progress can be immediately stopped, and the treatment repeated as many times as necessary. Life would by this means be prolonged indefinitely, provided that metastatic deposits had not occured before the commencement of the treatment. So far, cases able to bear the full strength required have shown no signs of recurrence. (2) Patients are not obliged to lie up, but are able to get about on the day following the application. (3) The current can be passed through almost any part of the body, and thus arrest growths which could not by any possibility be otherwise treated." Up to the present, however, this method of treatment—although, as I believe, full of promise—rests on far too limited clinical experience to allow any positive conclusions being arrived at as to its absolute value. Meanwhile, it may not be useless to review the respective utility of other remedial measures which may be employed in the cases now under consideration.

First, therefore, with regard to amputation of the cervix in the early stages of uterine cancer, the fact should not be lost sight of that in a very large proportion of instances the starting point of the disease is distinctly traceable, as Dr. Emmett has pointed out, to pathological changes commencing within the cicatricial tissues, resulting from parturient lacerations in the cervix uteri.

Dr. John Williams has clearly described microscopical evidences of the gradual transition from healthy to the malignant structure in his Harveian Lectures; and Mr. Jonathan Hutchinson points out that in many cases the first stage of cancer is that of inflammation, that all inflammations are infective, and inflammatory processes may pass by almost imperceptible gradation into malignancy. "In more than three hundred cases of cancer of the cervix, of which I have notes," observes Dr. Reamy, of Philadelphia, "but one occurred in a virgin, and but ten in married women, in whose cases I could obtain no evidence of abortion or child-bearing. Can anyone deny that such facts point strongly to the local origin of cancer, in these cases at least? And can it be doubted that injuries inflicted upon the cervix during parturition have a direct or remote connection with this origin?" Many years earlier the late Professor Montgomery, in a paper on the "Incipient Stages of Cancer of the Womb," pointed out that, as a general rule, the first discoverable morbid change, which is the forerunner of

[1] Abstract of a paper read at Leeds Meeting of the British Medical Association, August, 1889.

cancerous affections of the uterus, takes place in and around the muciparous glandulæ, or ova nabottri, in the cervix and margin of the os uteri.

Rokitansky remarked that cancer of the uterus generally limits itself to the vaginal portion and cervix in a defined and sharp manner. And he further observes: "The primitive seat of cancer is always the cervix uteri, and first of all the vaginal portion. The primary appearance of cancer in the functus uteri is limited to such extremely rare cases that we have just said remains a fixed rule." The late Sir James Simpson supported the same view, and in support of it quoted Dr. Walshe's observation: "Uterine cancer is commonly primary, and possessed of comparatively slight tendency to contaminate the system generally. In two important respects, therefore, uterine cancer presents conditions favourable for surgical interference. Still, however, in order that a case may offer any chance of success, several conditions seem requisite—viz., the diseases must be in an early stage; and secondly, the morbid structure must be distinctly situated below the line of reflection of the vagina upon the cervix uteri. The above combination of circumstances is seldom met with, because the medical attendant is rarely consulted until the disease has passed the limits in question. Nevertheless, of eight cases referred to in Simpson's monograph here cited, in which he thus amputated the cervix, seven recovered perfectly.

A similar conclusion is supported by more modern authorities, and as Hart and Barbour point out, we may, in accordance with the researches of Klebs, Waldeyer, Virchow, and others, trace the origin of all those malignant growths either to the cervical epithelium of the cervical glands, the deepest layers of squamous epithelium on the vaginal aspect of the cervix, the connective-tissue cells of the cervix or the epithelium of the cervical canal. With regard to the subsequent course of the disease, however, the evidence of later authorities is less unanimous and less satisfactory on this point. Thus, for instance, whilst, according to a recent editorial *resumé* of this subject in the *British Medical Journal*, Dr. John Williams maintains that the disease does not tend to spread upwards from the cervix, but rather laterally towards the broad ligaments and vault of vagina.

Recurrence after amputation takes place, as a rule, in the neighbouring connective tissue, and but rarely in the stump. Hence that authority's preference for supra-vaginal amputation of the cervix. The Germans are mostly opposed to this practice. Dr. Abel, after examining seven uteri extirpated by Professor Landan for cancer of the cervix, found malignant degeneration of the endometrium in all. Dr. Fränkel examined six cancerous uteri, and found that whilst the cervix was cancerous, the uterus was affected with glandular and interstitial endometritis: in other words, the endometrium was not cancerous. On the ground of the general pathological changes which he detected, he nevertheless advocated total extirpation of the uterus. His argument in this respect appears as weak as Dr. Abel's is strong.

Dr. Klein in similar cases observed changes in the endometrium, which he held to be inflammatory, not malignant, yet insisted that total extirpation was demanded in cancer of the cervix whenever that severe proceeding was practically feasible. Consistency of principles as applied to the results of observations, adds the writer quoted, therefore rests with Dr. Abel and Dr. John Williams; unfortunately, their conclusions are diametrically opposite. We need more observations on the condition of the endometrium in cancer of the cervix, and more records of after-histories where either of the above-mentioned operations have been undertaken with success." In this, however, lies the main difficulty with regard to this question, it being, as I have found by long experience, as a rule, extremely difficult to follow the history of our hospital cases once they are lost sight of after their discharge from the wards.

In my own practice I have during the past ten years only succeeded in tracing that history with more or less accuracy in twenty-two cases in which during that time I have amputated the cervix for cancer, or what I believed to be incipient cancer. In all these instances the patients thus treated recovered from the immediate effects of the operation, and were discharged as convalescent. In four of them the disease recurred either in the uterus or elsewhere within a year; in two it returned within two years; in one instance the patient returned two and a half years subsequently with a large cancerous ulcer of leg, from which she died shortly afterwards. In another it recurred two years later. Fourteen cases have continued, so far as could be learned, in good health after the operation.

These results must, I think, considering the nature of the disease for which the operation was resorted to, and the results of other methods of treatment, be regarded as fairly satisfactory. The question, however, of the general expediency of these respective plans of treatment in cases of uterus cancer can only be determined on similar principles to those which are commonly recognised and acted on in the treatment of other forms of malignant disease. Thus, for instance, no surgeon would be justified in amputating the cervix in cases where cancerous cachexia was well established, or where the disease was either developing with unusual force and rapidity, or had evidently extended beyond the cervical zone.

The constitutional symptoms of uterine cancer in its later stages need not be here enlarged upon, being general emaciation, sharp, pinched, anxious facial expression; yellow, semi-jaundiced discoloration of the whole surface, and the well-marked hectic and other unmistakable evidences of the cancerous cachexia. Nor in this connection is it necessary to dwell on the evidences revealed by local examination, when cancer has extended beyond the cervical zone, and when the characteristic pain, hæmorrhage, and pain, as well as the symptoms caused by the pressure of the enlarged displaced or adherent cancerous uterus, or consequent on the extension of the disease to adjacent parts, leave no room either for doubt as to the little hope as to the prognosis of the case. Once the cervical disease has attained the ulcerative stage, there can be no question as to its detection, though then commonly, but too late, when, on digital examination, the cervix is found lower than normal, the uterus being bound down in the pelvic cavity by adhesions to the surrounding tissues; the os open, its lips, if not already destroyed, tumefied, or else perhaps presenting the stony hardness characteristic of the schirrus form of disease. The cervical structure is then more or less deeply excavated; occasionally the entire os and cervix being thus eaten away before any suspicion of the nature of the case has called for examination. By the speculum, the characteristic, foul, irregular corroded ulcer, covered with a grey viscid putrilage, now comes into view; whilst if any possible doubt could then exist, this would be cleared up by the presence of the peculiarly fœtid ichorous or watery discharges attendant on open cervical cancer.

What I would, however, again desire to impress here is the possibility of recognising the earliest incipient stage of cervical cancer, long before any pain, hæmorrhage, or characteristics is observable, by evidences which were well described by the late Dr. Montgomery, but which are too often passed over by later writers, as well as by microscopic examination. On careful exploration at an early period in such cases, the margin of the os uteri is found hard, and often slightly fissured.

In the situation of the muciparous glands there are felt several small, hard, and distinctly defined projections, almost like grains of shot or gravel under the mucous membrane. Pressure on these with the point of the finger gives rise to pain or nausea. The circumference of the os uteri feels turgid, and to the eye presents a deep crimson colour; while the projecting points have sometimes a bluish hue. According to Professor Schuta, of Prague, it is possible to make an early diagnosis only by regarding every case of catarrh and erosion with suspicion, and by examining them carefully as to whether we can discover on the surface of the erosion a small nodule projecting, which is dark red or yellowish red, bleeding very easily. These nodules seem at first quite innocent; nevertheless, when excised they present, under the microscope, all the characteristic signs of cancer of the uterus. The future of this disease will be better if we operate early. This, however, depends on our early diagnosis, and for this purpose the cautious employment of the curette so as to bring away a sufficient amount fo the abnormal tissue for microscopic examination should be resorted to in every case of suspected or possible adenomatous or cancerous dengenerations. This diagnosis being thus established, the next question to be considered is the treatment to be adopted under ordinary circumstances, and as a general rule in cases of uterus cancer.

In this connexion the position and surroundings of the uterus should be borne in view, and especially important as Mr. Alban Doran has observed are the recent researches of Mierzaeiosky and Leber on tne dense network of lomphatic plexuses surrounding the cervix, and emptying their contents into two large trunks passing along the broad ligament to the obturator glands, and thus favouring the rapid extension of the cancerous elements into parts almost beyond the possibility of the complete removal of the infected tissues. There is, therefore, I fear little to be ultimutely gained by the more heroic procedure, and our main reliance must rest on the early recognition of the cervical disease, and its prompt treatment by the amputation of the neck of the uterus above the limits of the cancerous infection; or, as may possibly be proved by future experience, from the employment of the electric current before referred to. In a large number of instances cervical epithelioma, if sufficiently early recognised, may, I believe, be completely arrested by the infra-vaginal amputation of the cervix, and the free cauterisation of the stump, without the necessity for resorting either to Schroeder's flags operation, or to the super-vaginal method of accomplishing the amputation of the uterine neck, the mortality from which was four in thirty-seven.

At a meeting of the Obstetrical Society of Berlin, in October, 1886, Hofmeier reported the number and results of total extirpation by the same operator. The report included 118 partial amputations, with ten deaths—mortality 8.5 per cent.; and forty-eight total extirpations, with twelve deaths—mortality 25 per cent.

Four years previously Pawlik published a report of 136 cases of cancer of the cervix which had been treated in the first gynæcological clinics of Vienna by means of the galvano-cautery. The mortality from the operation was apparently not over 3 or 4 per cent. By amputation with the hot iron, Schroeder, out of thirteen cases, had an operation mortality of $7\frac{7}{10}$ per cent., and of the survivors 42 per cent. remained well at the end of eighteen months to two years.

Carl Braun and Simpson cite instances of patients who were operated upon in this manner, and who had continued alive and well for a quarter of a century. A few years ago this subject was discussed in the London Obstetrical Society, where Dr. Godson exhibited specimens from cancerous cervices which he had amputated, and in which there had been no recurrence of the disease after a lapse of six and three and a half years respectively after the operation.

According to Kuge and Veit, cancer of the portio vagenalis has a very slight tendency indeed to spread into the cervix, but almost invariably spreads out laterally into the fornices of the vagina and the ligaments. "What possible advantage, then," asks Dr. Duncan, "can be expected in these cases by removing the uterine body (which is unaffected) over that gained by the supra-vaginal amputation, which gets rid (as far as the uterus is concerned) of the disease? On the other hand, cancer of the mucous membrane of the cervical canal spreads up along the canal and into the uterus, whilst it only at a late period (or even not at all) attacks the os uteri." The removal of the affected cervix may be accomplished by the infra or supra-vaginal methods, and of these, under ordinary circumstances, I much prefer the former. In its performance we may use either knife, scissors, or galvano-cautery, or ordinary chain or wire ècraseur, with satisfactory results, although its use was objected to by the late Dr. Marion Sims, on the grounds that it makes a lacerated surface to heal by granulation, which takes a long time, often leaving the os tincæ contracted. Another objection to it is the uncertainty of just where we place the chain, which often draws in more tissue than we intend, and removes more than we wish. So great has been this trouble, that some of the German surgeons have given up the ècraseur altogether in operations on the neck of the womb, because the attachment of the bladder, and in some instances the posterior *cul-de-sac* of the vagina, have been injured, and even the peritoneal cavity opened by its greedy grasp. I have not myself observed the occurrence of the mishaps thus referred to by Dr. Sims in my use of the steel wire ècraseur. In amputation of the cervix, the patient being in the ordinary lateral semi-prone position, and the parts exposed by the duck-bill speculum, the uterus should be drawn down by forcible traction with a strong vulsellum until the cervix protrudes beyond the vulva, so as to elongate the structures and allow of the wires of the ècraseur being applied well above the diseased portion, and above this, again, the uterine neck should be transfixed by a stout wire ligature, to prevent subsequent retraction and facilitate the full use of the thermo or galvano cautery which I regard as essential. The advantages following the use of the actual cautery after removal of the cervix for cancerous disease are, I believe, unquestionable, but may probably be due, as M. Sèchillot has considered, to the creation thereby of an adventitious fibrous tissue of low vascularity, which is more or less refractory to morbid change, and acts as a barrier to the recurrence of the disease. With regard to the extirpa-

tion of the entire uterus for cancer, the limits of time and space here at my disposal do not permit of any attempt to discuss the respective merits or demerits of either supra-vaginal or abdominal, or those of the vaginal modifications of hysterectomy suggested for this purpose; though if either are to be adopted, the exceptional experience of Dr. Martin, of Berlin, cannot be lost sight of in favour of the latter, by which, in forty-four cases during a period of seven years, the results, excluding the immediate mortality of the operation, were nine relapses within the first year, four relapses at later periods, and thirty-one recovered up to the date of this report.

The earlier literature of the vaginal operation for extirpation of the cancerous uterus was ably reviewed by Dr. Condie, in the American edition of the late Dr. Churchill's work on "Diseases of Women." As this matter bears directly on the practical question now under consideration, and is now generally ignored, I may venture again briefly to recapitulate some of the facts there referred to. One of the first, if not the first, surgeons who performed this operation was Palletta. Subsequently it was performed once by Santer, twice by Siebold, once by Holacher, four times by Blundell, once by Barnes, once by Lizars, three times by Kecamier, thrice also by Langenbeck, once by M. Delpech. Of all the nineteen patients, sixteen died in consequence of the operation, one as late as the fourteenth day, most of them on the following, or third at the latest, some in a few hours, or even a few moments after the operation.

Velpeau says that the operation was performed twenty-one times in twenty years, and of all these not one of the cases was permanently cured (*Méd. Operatoires*, p. 162).

In a valuable communication to the London Obstetrical *Transactions*, "On the Extirpation of the Entire Uterus," in certain cases of cancer, Dr. William Duncan has collected from various authorities the particulars of a large series of cases of these operations, of which 137 were by the abdominal method, with 99 deaths (being a death-rate of 72 per cent.), and 276 were cases of vaginal extirpation, with 79 deaths (being a death-rate of 28.6 per cent.).

"Owing to the frightful mortality attending the abdominal operations for the removal of the cancerous uterus," says Dr. J. Reeves Jackson, of Chicago, in an able paper read before the last International Medical Congress, "not less than 72 per cent., and probably considerably more, it has been generally abandoned, except in a comparatively small number of cases in which the vaginal method is inapplicable.

The mortality of Kolpo-hysterectomy, according to the statistics compiled by Dr. Post, is shown to be 27 per cent. in 341 cases. This is 1 per cent. less than the result of the first 29 operations collected by Hegar and Kaltenbach, and 2.4 per cent. greater than the result in 256 cases published by Munde, in September, 1884. The statement has been made that the mortality of the operation is steadily lessening year by year. While this may be true, these tables hardly show the fact. In the case of a few operators, improvement has unquestionably occurred, but it is by no means general. In those who survive the operation, recurrence takes place on an average in about four months, and death in fourteen months.—(Sanger).

The conclusions with regard to the expediency of the entire extirpation of the cancerous uterus, arrived at by Churchill and Gendrin some forty years ago, are thus only too well borne out by the general results of the better and more scientific methods now employed for the same purpose and may be here cited.

"After," says the former, "a careful examination of the results of the operation, when the uterus is *in situ*, it is really difficult to find adequate reasons in its favour, except the repugnance which everyone must feel to give up entirely the hope of affording relief from the most agonising sufferings to which the female sex is exposed." —(Churchill's "Diseases of Women," p. 278.

"It is evident," observed M. Gendrin, "that the extirpation of the uterus is one of the gravest and most painful operations in surgery, since it is most fatal. It ought not to be undertaken except with great prudence, nor unless it is probable that the disease is perfectly removable. The signs of this limitation of the disease to the uterus, and of its mobility, are to be acquired by the use of every mode of examining the uterus, but unfortunately these means are not always trustworthy. Very able men (MM. Santes and Kons) have overlooked the extension of the disease to the ovaries and Fallopian tubes, which are often attacked when the body of the womb is affected. We must conclude that in many cases it will be wiser to abstain from the operation."

Even in extensive adenoma of the uterus, in which the cavity was filled and enlarged by the malignant villous outgrowth, and the patient exhausted and miserable from the pain, hæmorrhage, and fœtid discharge, I have, without resorting to extirpation, in several instances succeeded not only in relieving those symptoms, but also, as I believe, in materially prolonging the life of the patient, simply by thoroughly scooping out and removing the diseased structures. In two of these cases almost all the uterine parenchyma was thus so extensively scraped down as to leave only a thin sub-peritoneal shell, and after curetting, the raw surfaces were treated with chloride of zinc. It should be added that, although the disease ultimately returned, and that generally within a year, save in one case in which the patient survived for upwards of two years, yet the amount of comfort and relief to mental distress, as well as to intense physical suffering, thus afforded, was beyond question. At the same time there can be little doubt as to the propriety in some urgent and otherwise unrelievable cases of fundal uterine cancer, of resorting to whatever measure may afford any reasonable possibility of protracting life or of relieving suffering, Under such circumstances extirpation may be expedient, even if not capable of effecting in our hands all that has apparently been obtained in Berlin by this operation in the practice of Professor Martin. But at the same time whilst fully recognising his high authority on this subject, I would venture to reiterate my dissent from the sweeping conclusion he has formulated in a paper in the *Transactions* of the last International Medical Congress, in which he says: "I recommend the vaginal extirpation of the uterus as the operation and the means which we ought to apply in cases of cancerous diseases of the uterus, as long as the disease is limited to the uterus itself."

For my own part, bearing in view the enormous mortality too commonly supervening in operations for the extirpation of the cancerous uterus, whether by abdominal or vaginal methods, as well as the frequent recurrence of the disease in those who survive the immediate consequences of such operations, I cannot regard their employment as yet proven to be expedient or justifiable as a general rule of practice in cases of uterine cancer.

MEDICAL OFFICERS OF HEALTH: THEIR TRAINING AND THE CONDITIONS UNDER WHICH THEY SHOULD HOLD OFFICE.[1]

By G. E. J. Greene,

HEALTH OFFICER. FERNS, CO. WEXFORD.

I think it is generally conceded that the medical officer of a dispensary district, who is also medical officer of health (I speak now with special reference to Ireland not having had a very extended experience of the working of the Health Acts in the sister country), performs his sanitary work in a very slip-shod fashion. This negligence may arise from a variety of causes, such as incompetence, indolence, over work, or it may be financially to his credit to be, so to speak, "sanitarily amaurotic." This latter is to my mind the most potent factor in the maintenance of fever centres in many of our rural and urban districts. Take for example the case of a patient in affluent circumstances, but who is wholly regardless of sanitary laws, believing, in fact, such new fangled notions about disinfection, etc., to be mere passing crazes. He is the proprietor of a nuisance to which his next door neighbour happens to take exception, and calls in the health officer with the view of having him report it so that the necessary legal steps may be taken for its removal. Now considering the sanitary man is a large source of yearly income—chiefly by reason of his insanitaryness, and to proceed in the usual way, or even mention the matter, would give mortal offence, and ensure another medical man being called in next time. What is it probable the health officer will do under the circumstances? I will state what usually occurs. He generally says he is in a great hurry, and very busy remind him of it next time he is passing, or else inspects and does not report, and on being subsequently questioned on the matter pleads having forgotton it owing to multiplicity of work. A not unnatural course to adopt, remembering the sanitary man is seldom ill, is usually in poor circumstances, and has not the extended circle of his more wealthy neighbour. The foregoing is fairly typical where the sanitary officer's attention is not called to a nuisance by a printed notice from the sub-sanitary officer in which latter instance he is legally bound to visit and report. Medical officers of health should possess a diploma in sanitary science, obtained by passing a Government examination (mainly practical) in analytical chemistry, physiological and histological botany, animal pathology, geology, and sanitary engineering, to which might be added climatology, and perhaps bacteriology, should hold jurisdiction over a large area, be appointed by and draw their pay from Government, which pay should be sufficient to support them without their engaging in any other occupation. They should be designated medical officers of health, and have the option of promotion to better districts with higher pay after a certain number of years' service. It is needless to say they should be medical men first, but should enter into an engagement not to practice. It is well nigh impossible for a man, engaged in practice, and not having undergone any special sanitary training, to look after his district, suggest suitable remedies for the innumerable nuisances, etc., which exist from time to time, and keep himself abreast of the ever advancing tide of sanitation. The subjects enumerated as essential in a medical inspector of health's curriculum are, I believe, of obvious utility, and do not need to have their advantages set forth. I could enlarge the scope of this paper indefinitely, but I have crudily touched on a few of the salient points merely, the details of which can be further elaborated in subsequent discussion. In conclusion I would venture to suggest that the Parliamentary Bills Committee of the Association should have a bill introduced next session to Parliament, embodying some of the more practical points here advanced, provided they meet with the approval of the section.

[1] Read in the Public Health section of the British Medical Association meeting at Leeds, August, 1889.

CO-EXISTENCE OF DIPHTHERIA AND TYPHOID FEVER.

By Benjamin Walker, F.S.A.,

KIRKBY-STEPHEN.

M. A. C——, a healthy, well-developed housemaid, æt. eighteen, dislocated her shoulder on December 20th, and after reduction, she went into the country to take rest for a few days, living in a cottage provided with defective sanitary arrangements. I was next called on December 24th, and found her in bed complaining of languor, loss of appetite, and pain in the head, throat, and chest; I found the tonsils enlarged, and four pinkish-grey circular raised patches on the right tonsils, and one on the left; the lungs were in the "Stoke's stage" of acute pneumonia, characterised by harshness and roughness of the breath sounds; engorgement had not set in.

The tongue was coated down the middle only, and red at the edges. There was no pain in the abdomen, and the bowels were regular. Urine diminished, and of sp. gr. 10.20, faintly acid, rather dark, with a distinct trace of albumen; temperature 100°. During the next two days the patches on the tonsils extended backwards and forwards, involving the uvula and the buccal mucous membrane, becoming more dense, and of a duller grey colour; temperature 99°. The breathing was short and painful; the lungs were engorged and crepitant râles were general.

The urine became more scanty, with $\frac{1}{8}$ albumen, and of a deeper colour. Until the 8th day the case continued to give the usual signs and symptoms of diphtheria of a dangerous type. On the 9th day the girl felt quite prostrate; the headache increased, and she complained of pain in the abdomen and loins; this was accompanied by tenderness in those parts on gentle pressure; there was laxness of the bowels, with frequent vomiting, and the patient was in a very bad state.

I examined the skin daily, and on the fourteenth day found several typhoid spots on the abdomen, a few on the chest, and also on the forearms. The condition became more alarming; the breathing was much impeded by the diphtheritic lining of the throat, but on the twenty-third day the abdominal tenderness lessened, the stomach was less irritable, and the day following the patient coughed up a cast of about half the pharynx and that part of buccal mucous membrane on which the grey lining was deposited at the outset; it left a slightly red, raw, bleeding surface. During the next two days, the patch on the other side of her throat was coughed up, and from this time she began to improve slowly, but was unable to feed herself for a fortnight. She was kept in bed a fortnight more, and has since made a good recovery, except that the kidneys have remained weak, and albumen is present in the urine.

The interest in this case is the co-existence of the diseases and the severity of the diphtheria which attacked the girl first. Benzoate of soda, muriate of iron and tonics, were the chief drugs used, with glycerine of tannin for local application.

ON THE OXYIODIDES OF CALCIUM AND BISMUTH.

By Hugh Woods, M.D.

The oxyiodides of calcium and bismuth, the compounds to which I desire to call your attention, differ from the iodides, or salts of hydriodic acid, by the association of oxygen with the iodine; while, on the other hand, they differ from the iodates or salts of iodic acid, by their containing a much smaller proportion of oxygen.

But the point of difference which appears to me of the greatest practical importance is this, that the oxyiodides, as I shall call them, are more readily decomposed, so as to liberate the whole of their iodine, than is the case with the iodides and iodates in general. The constitution of the oxyiodides is not, however, the same in all cases, and therefore they need to be individually considered.

The greater readiness which the oxyiodides display of yielding up all their combined iodine gives to them a more powerful physiological action than the more stable iodine compounds possess. For I think it may be laid down as a rule, "That, where a substance possessed of powerful physiological action is combined with a comparatively inert substance, their physiological action is greater or less according as such combination is more or less stable." There are, no doubt, many exceptions to this rule; but in a large proportion of cases it would, I think, hold good. Of course such a rule must be very cautiously applied; but in the case of compounds of such a substance as iodine, I think it is applicable with but little reserve.

The physiological action of hypochlorate of calcium, or bleaching lime, is much more powerful than that of calcium chloride, and similarly, the action of hypiodite (or oxyiodide as I prefer to call it) of calcium surpasses that of the simple iodide. Hence I believe that iodine is much more efficiently and economically administered in the form of oxyiodide of calcium than as iodide of potassium or the like. In their antiseptic action, the oxyiodides compare favourably with such iodine compounds as iodoform, iodol, etc.; the readiness with which the oxyiodides give up iodine, when required, together with their unirritating and inodorous qualities, render them, in my opinion, decidedly preferable.

The characters and reactions of liquor calcis iodinatæ show that calcium oxyiodide is exactly analogous to that compound of chlorine, which, in an impure form, is known as bleaching lime. The formula, therefore, is $Ca\,OI_2$—that is to say, an atom of calcium is united with one atom of iodine by one link, and by the other link with a group consisting of one atom of iodine attached to one of oxygen, and analogous to hydroxyl. The formula of calcium oxyiodide, therefore, is :—

$$Ca\begin{matrix}-I\\-OI\end{matrix}$$

the monad iodine, together with the monad group OI being separately attached to the dyad calcium atom.

Liq. calcis iodinatæ is a solution of this compound, and it is only in solution that I have been able to prepare it pure. Any acid added to liquor calcis iodinatæ causes its decomposition with deposition of the whole of the iodine in the solid form; just as acids set free chlorine from bleaching lime. Water acidulated by $\frac{1}{600}$ of its bulk of hydrochloric acid sets free iodine from liquor calcis iodinatæ, and hence it is evident that the action of the gastric juice upon it produces calcium chloride and free iodine. Boiling converts liquor calcis iodinatæ into a mixed solution of iodide and iodate of calcium, and the addition of an acid then only causes a slight reddening instead of a black precipitate as before. The insoluble iodate also soon deposits in crystals on the glass.

I find liquor calcis iodinatæ useful as a test solution for urine, etc.; in the first place as detecting even a minute amount of *free* acid, while litmus paper does not distinguish between the acidity of acid salts and that due to free acid; secondly, it serves as a good clinical test for phosphates, which it precipitates at once, and especially if heat be applied. The milkiness which sometimes appears when liquor calcis iodinatæ is diluted with ordinary drinking water, is due to the presence of phosphates.

As a medicine, liquor calcis iodinatæ is useful in the cases in which iodine or the iodides are administered. It acts beneficially in chronic rheumatism, gout, syphilis, strumous disease, goître, and very many other affections. I have already alluded to the decided advantages it has over the iodides of potassium, etc., and its superiority, for internal administration, over the preparations of pure iodine, such as the tincture, is obvious.

Liquor calcis iodinatæ has a most unpleasant taste when diluted, but, if desired, it can be prescribed with various tinctures and other drugs, but not with the incompatibles of the iodides, or with any acid. The antiseptic action of liquor calcis iodinatæ makes it useful as an application to wounds and sores, and also as a paint to the throat in tonsillitis, diphtheria, etc. It is well adapted for injections into strumous glands or the enlarged thyroid, and also acts beneficially when applied outwardly in such cases. I have been told that it relieves neuralgia when applied over the painful nerve, but I have not yet tested its anodyne properties, if it has any.

Liquor calcis iodinatæ possesses the powerful antiseptic and deodorising qualities of free iodine, without the irritating and staining qualities of the latter. Liquor calcis iodinatæ contains sixteen grains of iodine in each ounce, and its dose is, therefore, about five to twenty drops. I do not find that it readily irritates the stomach, but it is probably best given after food, unless its direct action on the stomach mucous membrane is desired.

This preparation is much cheaper for use than the iodide of potassium, the price being 3*s.* 6*d.* per pound, as compared with 14*s.* for the iodide of potash. Of course the proportion of iodine present is very greatly less, but it is in a more active form, and hence the dose of iodine given is necessarily but small comparatively. I have had many favourable reports of it, and, as yet, only one unfavourable. I shall be very glad to hear any reports of it from those who make trial of it, and I recommend it as well worth an extended trial.

The chemical composition of red oxyiodide of bismuth is approximately represented by the formula Bi O I., that is to say, one atom of triad bismuth is connected by two links with an atom of dyad oxygen, and by its third link with an atom of monad iodine, thus :—

$$Bi\begin{matrix}=O\\-I.\end{matrix}$$

The constitution of this oxyiodide is therefore not of the same nature as that of calcium oxyiodide, although it is somewhat similar. The constitution of the yellow oxyiodide of bismuth (as I call it) is very complex, and I am not able to give a formula of any practical value. It contains only twelve grains of iodine in each ounce, which is a vastly smaller proportion than we have in the case of the red

oxyiodide. It is formed by treating subnitrate of bismuth with a solution of calx iodinata, and is made of a constant composition. The presence of twelve grains of iodine in each ounce suffices to make the powder decidedly antiseptic, and hence makes it much more valuable than the subnitrate in many cases. By mixing together the red and yellow oxyiodides in suitable proportions, we can obtain a powder of any intermediate strength as regards iodine.

Both of these oxyiodides are decomposed by acids, setting free all their iodine; and they readily enough give up their iodine to other bodies. They are, however, quite stable enough for preservation for all practical purposes. They are not altered by boiling.

These oxyiodides of bismuth are very fine insoluble powders, of a copper-red and a yellow colour respectively. They are absolutely free from either taste or smell of any kind. The uses of the oxyiodides of bismuth as external applications are very similar in many respects to those of iodoform, but one or other of them can be used in a great many cases to which iodoform is inapplicable, and their antiseptic action is much more decided. Their freedom from smell gives the oxyiodides of bismuth one important advantage over iodoform, and the yellow preparation can be used with perfect freedom without any risk of poisonous effects. The red oxyiodide is intended only for external use. It can be applied in the form of powder, or as an ointment, which is prepared at my suggestion, of a strength 1 in 10. A similar ointment of the yellow oxyiodide is also prepared.

The oxyiodides of bismuth form most excellent applications to wounds, sores, and ulcers of all kinds. Where a powerful antiseptic action is required, the red one is preferable; and, on the other hand, the yellow one can be more freely applied to extensive wounds than the red oxyiodide, which, if carelessly used over a large raw surface, might produce iodism. I have not, however, observed this result as yet.

The oxyiodides of bismuth are very efficacious in eczema, intertrigo, sweating feet, chapped hands, and the like. They are valuable in many skin affections, and the red oxyiodide acts well in parasitic skin diseases. The yellow powder is also suited for internal administration, and may be given with benefit in some affections of the stomach, such as cancer, gastric ulcer, and chronic morbid conditions of the mucous membrane. Where an antiseptic action is required, it is preferable to the subnitrate. It can be given in doses of from five to twenty grains, in the same way as the subnitrate is given.

In the three preparations to which I have called your attention, we have a complete series of compounds for the administration and external application of iodine. Except for purposes of counter-irritation, these preparations are well suited for producing the various effects which we can obtain by the help of iodine. The above have not the irritating and staining properties of the free iodine preparations; while, at the same time, they allow the iodine present to exert in full its useful influence.

I may say in conclusion, that the red oxyiodide of bismuth has already been recommended by others than myself; but I have arranged for it to be manufactured at a considerably cheaper rate than before. I believe that I am the first to introduce the other two preparations.

The above preparations are being manufactured, at my suggestion, by Messrs. Willows, Francis and Butler, 101, High Holborn, London. Specimens of them, and descriptive leaflets, will be found in the Museum.

THE HYGIENE OF MIDWIFERY.

By John Dysart McCaw, F.R.C.S.

"Clean hands" is the motto of modern obstetricians. The older midwifery writers preached the doctrine of chastity: "Thine is a high and holy calling; see that thou exercise it with purity." The professors of obstetrics in this age urge with equal earnestness the cleansing of the outer man with subtile chemical solutions. This idea of the practical application of Listerian principles to the practice of midwifery did not originate in England. The first impetus to the study and practice of obstetric antisepticism in this country followed the publication in the year 1884 of two admirable reports on "Obstetrics," by Dr. W. C. Neville and Dr. Arthur V. Macan, in the *Dublin Journal of the Medical Sciences*.

Hoch first published his conclusions as to the relative value of the different disinfectants in 1881. From his experiments it became known that weak solutions of corrosive sublimate formed the most powerful of all known measures of disinfection. This led to its use for *obstetric* purposes. The results of the first trials came from the Breslau clinic, and the methods of using it there were conveyed to the readers of the *Provincial Medical Journal* by me in October, 1884, in a short paper on "The Practice of Obstetric Antisepticism at Home and Abroad," in which it was clearly proved that the adoption of antisepticism in midwifery had caused an *amazing* decrease, both in puerperal mortality and in puerperal morbidity. At the International Medical Congress in 1884, Dr. Ingersley, Copenhagen, gave an interesting summary of his researches into puerperal mortality, in the towns of the Danish provinces, and in Copenhagen for seventeen years, and made a calculation of the deaths from puerperal fever in the towns, in the country districts, and in the maternities; this was checked with the greatest possible care, and showed an evident decrease in the puerperal mortality which *undoubtedly* was due to a more strictly antiseptic conduct of labours, even outside the maternities. Since Drs. Neville and Macan (I believe these gentlemen deserve the credit) spread the principles of this continental practice amongst the medical profession of this country, *the toilet* of the parturient woman and her attendants has received more than ordinary attention.

Very little if any advance has been made in recent years in antiseptic midwifery; the time-honoured napkin has long since been discarded for the more comfortable "sanitary towel," "or the gauze-bag of sublimate wood-wool," and tiny pellets are now carried in the pocket to make our antiseptic solutions of any required strength at the bedside. Ablution is not now regarded with horror by the patient and her friends, but nothing really novel has *lately* been suggested. Strict cleanliness is the great secret of success in midwifery work. Both patient and attendants must be scrupulously clean. This is of first importance whether antiseptics are used or not. Outside lying-in hospitals —in private practice—with this principle before one's mind, and making it a rigid rule, and with good hygienic surroundings, the *constant* observance of a hard-and-fast antiseptic routine in midwifery practice is not to my mind absolutely essential to successful results. I am, however, strongly of opinion that in all public maternities and lying-in hospitals the most strict antiseptic precautions ought to be always observed. In private practice, where the practitioner or nurse may have been recently brought into contact with scarlet fever, diphtheria, erysipelas, or indeed any zymotic disease, preventive measures must be also adopted

before, during, and after confinement. Dr. Cullingworth deserves the thanks, both of his professional brethren and the public, for his forcible and practical addresses on this important subject to the students of St. Thomas's Hospital last October, and to medical practitioners at the last meeting of the British Medical Association. We cannot insist and impress too much on our patients, and nurses trained and untrained, the absolute and vital importance and necessity of antiseptic cleanliness in midwifery practice.

In my own practice, extending over some two and twenty years, I have had a very happy and perhaps somewhat singular immunity from death among my midwifery patients. It has been my good fortune to have attended about 2,500 labours without a maternal death. This pleasing record I attribute mainly, if not solely, to a thorough observance of as perfect cleanliness as possible, and a firm resolution to keep in mind all likely sources of contamination to my patients, and the best means of avoiding and preventing it.

Special Articles.

THE CONTROL AND CURE OF INEBRIATES.

By Alfred J. H. Crespi, of Wimborne.

The Inebriates Acts, from which so much was naturally expected, expire at the close of the present year, and unless allowed to drop will have to be renewed. It is understood that those Acts have not been so elastic and useful in practice as was hoped, and that attempts will be made to introduce fresh clauses, which will increase their value. Some of the proposed alterations do not, in my opinion, enhance their value, and in the following article I have endeavoured to point out a radical change imperatively demanded if real good is to come from the Acts.

Estimates have been frequently attempted as to the number of habitual drunkards of both sexes in the United Kingdom: all place the total very high. I shall not venture to frame a fresh estimate, nor to formulate any definition of what constitutes habitual intemperance: and for my present purpose it is enough that a very large number of persons frequently drink to excess, and by so doing injure themselves in health, morals, and pocket, while they are a constant source of anxiety, sorrow, and loss to their relatives. Whether the temperance movement is advancing or not, whether drunkards are more or less numerous is immaterial to the object of this paper, which concerns itself solely with the restraint of inebriates, so that their friends may cease to be plagued by them. I am aware that we have three agencies at work to control drunkards—the police, who take charge of a large number and after detaining them a few days, release them; retreats under the Inebriates Acts, which receive a few, a very few victims of this vice, and keep them from mischief, and so far good, but before admission can be obtained, the drunkard must voluntarily give up his liberty, and the magistrate must make him clearly understand the full import of his action, and, in the last place—a certain number of wealthy drunkards are, with infinite pains and usually at enormous expense, confined in the private houses of friends or in those of medical men; and relays of attendants, whose duty it is to watch over them, succeed one another night and day. The first system is good and necessary and, as far as it goes, effectual, but it is only temporary: the second is expensive and only reaches a very small number; one objection to it is that the drunkard must give up his freedom of action and movement, and *that* he will not often do: the third plan is only suited to the very rich: doctors only care for inmates who can pay well, and when it comes to two or three attendants to each resident patient the expenses range from £400 to £800 a year, besides this the patient's clothes, books, and miscellaneous requirements have to be provided, and a grand total of say from £500 to £1000 a year is reached. Busy doctors, greatly preoccupied with professional engagements, will not undertake cases at moderate remuneration, alleging that otherwise they do not pay, so that, to get proper treatment and attention, the charges are high, indeed enormously in excess of the means of all save a few rich families, while even then the restraint is not of a kind to be of real value.

My strictures may seem strong; I do not mean them as strictures, but can any one deny that most of the people engaged in the management of retreats for the intemperate think rather of their own profit than of carrying on a great reformatory wish? When I just thought of writing this article, I wrote to many managers and proprietors of such houses, and in no case did I receive any information; most of the persons addressed did not reply. One or two sent prospectuses; while one or two favoured me with brief and not particularly courteous answers. On writing to one more polite a second note of inquiry, he with charming courtesy, recognising my hand-writing, did not open my letter, but forthwith returned it. Candidly I would not send any inebriate to an establishment of which I did not know something favourable.

I once saw an officer, whose parents had put him in the house of a country surgeon in Gloucestershire, at the patient's own desire, indeed in a house of his own choice: the terms were high, but there was no effectual restraint. The next day the young man gave his keepers the slip, and was not found for some time: when I was sent for professionally I found him lying on the floor of a room in a large hotel: he was screaming and kicking frantically and was quite drunk. I succeeded in restoring him to his friends. In another case, in which I was consulted—that of a profligable officer in South Devon, money was squandered—no other word is applicable—in providing experienced attendants who were under no real discipline. At last I got the services of a retired Corporal Major of the Royal Horse Guards—but no permanent good was done, for the inebriate used to drive to one of the many small towns near and order his servant to purchase bottles of spirits. In short the master had the command of money and servants and was practically a free agent, and under the circumstances attempts to control him were like trying to empty a pond with a sieve.

Perhaps it ought to be made clear before going farther, that by inebriety should be understood habitual excess in any narcotic, or narcotico irritant, like chloral, opium, and bromide of potassium. By the way, though perhaps irrelevant to the present subject, Dr. J. C. Reid, an elderly medical practitioner, now I believe deceased, once mentioned in a paper read before the British Medical Association, that at one time inebriates could be sent into a lunatic asylum for three months. This power seems now to be taken away. This able practitioner in the same paper remarks that, though when he wrote it he was sixty-three, he had only known four victims of intemperance, who were ready of their own free will to go into an inebriate asylum; in other words, a busy and experienced practitioner might not oftener than

once in ten years meet with one inebriate who was ready to sign away his liberty even for his own good.

What we want is establishments to receive and detain inebriates, on the representation of their friends and in return for moderate charges. While in the home the patient should be absolutely unable to get out or to obtain stimulants, and his forcible detention should not be a matter over which he had any control: no declaration on his part should be necessary: promptly, cheaply and certainly, the magistrates should, in all suitable cases, have power to commit the inebriate to a proper place for not less than one month, nor more than six, not so much for his own protection as for that of his friends. Some time ago a physician of good standing in the Metropolis read a paper, in which he thought that he proposed a satisfactory solution of the difficulty by suggesting that written notices, according to a given form, should be served upon the neighbouring publicans warning them, at their peril, not to supply stimulants to the inebriate named in the notice. This paper was favourably received and commented upon while a rejoinder of mine fell dead: in my reply I endeavoured to show that in a small village it might be useful to serve such a notice on the two or three local publicans, but what about a great town where the inebriate would not be known to one publican in twenty, and where beer shops and grocers supplying stimulants are numbered by hundreds?

What, for instance, about Wimborne, where I am writing, which stands in the midst of a dozen other towns, not half an hour off by train, and one of them—Bournemouth—with a hundred drink shops, while another—Poole—is little less prodigally supplied? What use would it be to serve notices on local publicans when the inebriate could make his way to Wareham, Blandford, Ringwood and Christchurch in half an hour? Nor would such notices prevent the inebriate from getting a supply for home consumption.

The way must be cleared before approaching the discussion of my plan. In the first place, an immense amount of sheer nonsense and pseudo religion—cant in short—is talked on the temperance platform: the drunkard is held up to public sympathy as a poor deluded creature, longing for reformation: and society is often represented as banded against him, tempting him to drink, overcoming his scruples and ridiculing at his efforts to keep straight. The fact is that thousands of drunkards are notoriously persons of low moral type, with no good resolutions, no pure purpose: they like drink and they will have it: shame they no longer feel, and it is absolute rubbish to sympathise with them and regard them as suffering angels. Whatever his original position in society, or his education, the drunkard of both sexes is a miserable object—his own deadliest enemy—as long as we treat inebriety as a failing we shall do no good. Nor is much gained by looking upon confirmed intemperance as a disease—it may modify our view of the sufferer's guilt, but can hardly change the treatment adopted or reconcile his friends to his follies. "You know my failings" said, the other day, a miserable, degraded lady who for twenty years had been a misery to her family. Her failing forsooth! her low, degrading vice, indulged in, in the face of every good influence and of the most excellent surroundings. "Don't let her know that you think she drinks, it would vex her," once said a young lady to me, when I was called in to see her mother, a confirmed drunkard, who had got through a bottle of brandy that very morning before breakfast. "Don't scold me; I can't bear it; I am very naughty I know"—I have again and again heard of drunkards saying.

The drunkard can or he cannot control his appetites. If he can and wont, he is vicious, and should be severely punished. No doubt the effort would be severe, but in most cases the control, given a sufficiently potent motive, can be exercised, and I fancy that if the drunkard knew that every act of self-indulgence would be followed, in due course, by a sound flogging, outbreaks would be rare. If the drunkard cannot restrain himself, then he is a lunatic and a danger to society, and he should be treated accordingly. I have seen hundreds of drunkards and closely followed the career of many for years, and the low tastes, the indifference to the feelings of others, the untruthfulness, and the craving for present self-indulgence at whatever future cost have dried up my sympathies. Too often the drunkard does not care who pays the penalty of his vices.

"You ought to bring good moral influences to bear," people retort. "Talk to them; reason with them; cheer them up; help them to keep their good resolutions." All nonsense. Most drunkards should be locked up, and made to see that they are a menace to society, and must be protected from themselves for the sake of their friends. We must understand the heinousness of drunkenness, its penalties in this world and the next, its loathsome character, and its dangers, and then we shall be able to adopt effectual measures for the punishment of its victims, but not so long as we cant can we do anything.

Then the lawyers interpose: "The liberty of the subject must be respected; it would never do to lock up a man unless with his own consent. Then what is to be done with his property? Trustees must be appointed, a court of inquiry must sit." In short, if they are listened to, such complicated, costly and tedious machinery would need to be set in motion, that the Acts would be totally valueless in the case of the countless thousands of inebriates, whose circumstances do not admit of vast sums of money being squandered. Is the law generally so merciful? Is the liberty of the subject so religiously guarded? Suppose a man enlists: he soon learns that trifling misconduct means three months' imprisonment, and that absence without leave is not soon overlooked or expiated. Why a summons can be taken out against the highest persons in the realm, and they must obey it at any cost. It is only the drunkard whose liberty we treat with such scrupulous delicacy. As soon as he is mentioned we feel deep commiseration for him, but not for his friends—he may drink, waste his and their substance, and occasion them great suffering, and we give them no redress, no protection.

"What! punish a man for drinking!!! Punishment should not be thought of unless it is reformatory: you should reclaim not punish." And are the friends to be left out of the reckoning? are they to suffer, as I have known them do, a world of misery extending over many years, with no improvement, no hope of reformation. Are parents to be called upon to pay thousands of pounds, to meet bills wantonly run up in defiance of strict injunctions to the contrary by drunken sons?

What we really have is something of this sort—a large body of working men and women, who are drunkards, and who deliberately set themselves to drink when they can get stimulants; they are too poor to be taken into the present inebriate asylums under the Acts, nor would they consent to enter, and the managers of those institutions do not want them. We have also a large number of men and a fair sprinkling of women of the middle classes, who are

ruining themselves by intemperance. As a broad rule these people are irreclaimable, and it is useless to get them to sign the pledge, and to attend temperance gatherings. Now and then they conduct themselves fairly well for a time, then there is a relapse. The history of these cases is simply one of rapidly accelerating degradation until the end comes. For all I know to the contrary the number of these people may be as low as 10,000 or it may reach 100,000; probably nearer the latter. Every medical practitioner knows this miserable, degraded type, and has seen scores, perhaps hundreds. I certainly have. "Why" said a drunken officer to me the other evening "should not the poor man have as much beer as will do him good? Why did they call the horse that won the Derby, Donovan? Why should public houses be closed on Sundays?" The Major hereupon looked at me very sapiently, and propped himself up against a house to avoid falling. Every night after dinner he is in that condition—his pay, his private means, and all the money he can squeeze from an elder brother goes in this fashion, and nothing can be done to restrain him. Then another young man I know sells, when in the humour, everything he can lay his hands upon—clothes, books, boots, college prizes; and he will borrow from anyone, who will trust him a couple of shillings. His father pays for a handsome coat, which finds its way to a secondhand dealers and fetches three shillings; a waistcoat brings in eightpence, and a pair of trousers a couple of shillings, while a large and costly book only commands a shilling. But he would not go into an inebriate asylum, and of course the liberty of the subject must be respected, so that he cannot be forcibly detained unless by the police, who occasionally find him drunk, and then give him a night in the lock-up; and his friends have to pay, in the shape of fines and costs, for the accommodation thus provided.

The *British Medical Journal*, some months ago, had the following remarkable paragraph, which bears on the subject of this article. I have freely abridged it:—"The records of our police-courts, with their enormous mass of frequent offenders or 'repeaters' charged with drunkenness or offences connected therewith, are striking. The remarkable figures published by Dr. J. Francis Sutherland, relating to Glasgow, are a lay sermon of ominous significance. We learn that there are 10,000 commitments of women in that city every year. Each of these women is, on the average, convicted three times, and the mean period of imprisonment is seven days. About forty per cent. of these Scottish gaol-birds have had from 11 to 800 previous convictions recorded against them. What does this mean? Simply that, so far from cure or reformation, or even deterrence, these short sentences enable the prisoner to recover from the exhaustion of the last 'drinking bout' and send him forth recruited, invigorated, and fit to recommence his vicious indulgence. Such treatment of a pathological condition confirms rather than cures the inebriate habit. The establishment of homes, at the public charge, for the scientific care of these police-court *habitues*, would be more economical and effectual."

As I have said above, and as I want to insist upon, we must have a simple, quick, and easy method of dealing with these deplorable cases; and what could be better than the following? Let any person who stands in the relation of parent or child, brother or sister, or guardian or trustee to an inebriate—whether the latter is of full age or not—have the power to apply at the nearest police office for a form, in which name, address, occupation, and so on of applicant and of the inebriate, should, in due course be set forth. A summons should then be issued in accordance with these particulars, and be served on the inebriate. When the case came on for hearing, the magistrate should have absolute power to ask for and to obtain information as to the defendant's history, habits, and circumstances. Of course the application should be supported by proper witnesses and reliable evidence. The magistrates would soon eliminate the cases in which malice or fraud was the instigating motive; moreover the defendant would have the right to make his defence, and if possible, to clear himself. But, unless I am totally in error, I believe that in nineteen cases in twenty the inebriate would express contrition, seem very much frightened, and promise to amend; very rarely indeed would he plead that he was the victim of a conspiracy. Then, according to the circumstances of the case, the defendant should be ordered to be detained from one to six months to begin with; when indigent, the expenses should be defrayed out of the rates; when better off, he could have greater privileges, and be charged a moderate, a very moderate sum. As for places of detention, what could be easier than to provide special departments in gaols or lunatic asylums? At first such special departments might only be added to a few prisons or asylums; after a time, if necessary, to more, and finally, special institutions could be built and confined to this class.

What I want to make clear is that I am not proposing to treat these persons as criminals or lunatics, but as inebriates detained primarily for the protection and relief of their friends; while in the institution they should have books, papers, and letters, and see their friends, but they should be unable to leave till their sentence had expired. I am certain that were such institutions opened they would soon be crowded, and thousands of families would be relieved from a load of misery.

The mere fact that the applicants would in the main be relations would prevent outsiders from interfering, but it would also protect the defendants. A father could, for example, set forth that his son had for six years been an inebriate, incurred heavy debts, neglected his occupation, and caused great anxiety. In many cases I can speak positively that the evidence of guilt would be overwhelming and unanswerable. Occasional acts of intemperance would be totally different, and would not be held to justify incarceration. No doubt it might happen that occasionally the charge would not rest on sufficient evidence; sometimes, too, malice might instigate it, but the magistrates would soon eliminate these cases.

As for property, little difficulty could generally arise. As the inebriate would not be a criminal, he would be at liberty to see letters, documents, and lawyers, and while under restraint could transact any necessary business, while his friends would not have the unrestricted control of his property, though they might use some of his things. If the wish to appropriate his property was the motive of the action, the defendant would be the very person of all others most likely to know, and the services of a clever lawyer would be retained, and the latter would not neglect to make the most of the information given him by his client. But the property difficulty would not often occur, for in the vast majority of cases the very ground of the application would be the extravagant and bad habits of the inebriate, and detention would be demanded for the protection of his friends. At most it could only be a question of the use of horses, books, and house for a very short time, and even that would in great measure be got

over by the inebriate being able to give directions as to their management. If he refused to be reasonable, and, as might occasionally happen, would not make proper arrangements, his friends might apply, at his expense, for the temporary management to be entrusted to a relative, lawyer, or friend, though as soon as the magistrates were satisfied as to his habits his detention might commence. This question of the management of property is just that one, however, on which the lawyers will do their best to wreck the scheme; no one who is sent to prison for a few weeks for some trifling lapse from the right path is allowed to ask for acquittal on the ground that he has a horse or a house; and yet I greatly fear that the custody of a little property, in one case in twenty, will be held to be a serious matter, and will ruin the proposed reform unless the detention of inebriates is treated on sound, common-sense principles. When the amount of property is considerable, and the inebriate has been confined several times, provision might be made in the Acts for the appointment of trustees, with almost absolute control, but their appointment would seldom be necessary.

One class of cases I have not dealt with, and a very large one, too—that of confirmed low-class inebriates, whose friends did not trouble to move, or perhaps there might not be any friend to take the initiative. Here I think the local police authorities should have power to take the initiative, and instead of sending a person to prison 200 times, as has frequently happened before now, they could apply, in due form, to the magistrates for an order to commit the inebriate to an institution for six months, the expense if necessary to be defrayed out of the rates.

A friend of mine has, in a short time, sent a woman to gaol thirty-six times for being drunk and disorderly. Now I contend that the law urgently needs alteration, and that it is disgraceful to see the same wretched inebriate in the dock time after time. Something more effectual should be attempted.

No doubt a great deal will be made of the disgrace to the family, and we shall be told that forcible detention in an inebriate institution would be insufferable. Now, I ask, does anyone suppose that a man's habits are a secret to his friends, servants, employers, and neighbours? Many rich families delude themselves with the belief that the habits of a scapegrace son or abandoned daughter are a profound secret, while the decorous servants, who are alone supposed to be behind the scenes, have long ago told all the other servants in the neighbourhood the whole tale, and in this way half the inhabitants of a small town are in the secret, and follow its development curiously.

The need for such institutions as those I am advocating is urgent. The present Inebriates Acts could go on; private medical practitioners, with contingents of highly-paid attendants could be resorted to in proper cases; and the police might still look after the occasional riotous drunkard; but we require something more to reach the overwhelming masses of inebriates, who cannot afford to pay a medical man for very imperfect supervision vast sums—I do not say exorbitant sums, for the treatment of such cases in private houses is harassing and expensive, and must be liberally paid for to make it worth while embarking upon it.

Were some of our temperance associations to give their attention to the matter, and promote the passing of an Act that would meet the requirements of the case, they would do a great and useful work, and perhaps, in the long run, promote temperance more effectually than by a crusade carried on chiefly among people who have already signed the pledge and have no temptation to break it. Temperance meetings will not do inebriates any good, nor will they reach the latter. Much must be left to the discretion of the magistrates, for any attempt to frame an act so comprehensive that it would cover the whole ground, and deal with all the possible difficulties and complications of such cases, would infallibly lead to its being so cumbrous and complicated that, though it would find plenty of work for the lawyers, it would not protect the public. Moreover, as the magistrates would have full power to dismiss the application on the ground of insufficient evidence, unsuitability, or malice, the liberty of the subject would be effectually protected. Lastly, in cases of possible fraud or malice, the penalties attaching to perjury would necessarily be incurred by the applicants, and conspiracy need not often be feared.

Such an extension of the Acts as I have roughly sketched out would give the necessary elasticity and completeness, and would make them a boon to the nation, instead of as at present, a delusion.

HEALTH RESORTS OF THE WORLD.

XXXVIII.—LYNMOUTH AND LYNTON.

(NORTH DEVON.)

By H.N.S.

Lynmouth! What a charm has that name to the lover of the picturesque who has ever visited its glorious bay. Have you ever admired the view of Matlock from the Heights of Abraham, wandered through lovely Dovedale, tramped across the Yorkshire Moors, penetrated the solitudes of the Lake district, feasted the eyes upon the gardens of Alton Towers, strolled in the glens of the Isle of Man, climbed Malvern's "lonely height," or walked through the woods of Bournemouth? If so, imagine all these beautiful spots concentrated within walking radius of each other, and placed where the glorious billows of the Atlantic for ever add grandeur to the scene, and you may form some idea of the scenery of this English Switzerland.

Far from the reach of the cheap tripper, the piano organ, the niggers, and the thousand and one annoyances of an ordinary watering place, twenty miles from everywhere, and inaccessible from the land side except by coach or carriage, this peaceful spot lies nestled at the foot of the cliffs, with its neat white houses, clean, well-kept roads, and comfortable hotels; and its civil inhabitants are ever ready to welcome and provide for the comfort of the tourist who, wearied with the bustle of every day life in some smoky city, finds his way to this haven of rest. The writer of this article first visited Lynmouth during a stay at Ilfracombe. The inhabitants of that fashionable and excellent resort are apt to tell their visitors that "you can see Lynton and Lynmouth in a day, and return by the same coach in the evening." To one who knows anything of the district the above advice is about as good as telling a provincial bumpkin that he could see London during a day trip and return home satisfied that there was nothing left worth staying for. There are several ways to reach Lynmouth, viz: by Great Western or South Western railways to Barnstaple, and thence by coach; by the same lines to Ilfracombe, and coach beyond; by Great Western railway to Dulverton, with a coach ride of twenty-five miles; or by boat from Bristol or Weston-super-Mare. This latter route has its disadvantages, as, there being no

pier, passengers are landed by means of open boats which is most inconvenient, besides which the captains of the steamers plead various excuses for neglecting to call at times, and so carry the unsuspecting traveller as far as Ilfracombe against his will. There has been some talk of promoting a company to build a pier, which would be of immense advantage to the place, and would doubtless prove a profitable speculation.

Two lovely valleys lead out from behind Lynmouth, and down each of these comes a branch of the Lynn, the two streams uniting just near the Lyndale Hotel, and forming a foaming torrent, the brown waters of which tumble headlong over the boulders close beside the village street, and so reach the sea in the centre of the bay. The sides of the valleys above referred to are one mass of trees, beneath which are ferns of every variety in luxurious abundance; whilst on the immediate sea shore the Foreland stands out barren and rugged, but nevertheless looking charming in the sunlight of an autumn day. The main street of Lynmouth is most picturesque, especially near the beach, where the sea at high tide flows to within a few feet of that comfortable little hostlery "The Rising Sun" and its adjacent cottages; and it is no small compliment to this portion of the village to have been selected as the frontispiece to that splendid work "Picturesque Europe." A small jetty runs out from the main road, and at its end is a quaint tower with abundant loop-holes and machiolations. This was erected by General Rawdon, and is a copy of one on the Rhine.

Within a short distance of Lynmouth, and lying under the Foreland, is a splendid stretch of beach known as the "Sillery Sands," approachable by a path leading down from the Countisbury road. By some unaccountable neglect this path as it nears the shore has been allowed to fall into decay, and the sands are this season inaccessible for that reason. It is to be hoped that this may be remedied before another year, or an awkward accident may happen to a too venturesome visitor.[1] Four hundred and twenty feet above Lynmouth is the village of Lynton, situated in a sort of dip between two enormous hills. This village can be reached by a zigzag and almost perpendicular path, available for foot passengers only, or by the more circuitous coach road which seems scarcely less steep. To obviate the difficulty of transit between the two villages, the enterprising proprietor of a well known periodical (which is anxious for a weekly sale of half a million) has lately erected a lift, which, when completed, will doubtless be a great convenience for invalids, children, and luggage; but beyond making an ugly scar on the face of the cliff, which will take years of judicious planting to heal properly, very little has yet been accomplished.

Lynton is much larger than Lynmouth, and contains some splendid hotels, besides numerous comfortable boarding houses. The views from here, embracing the Bristol Channel, the valleys of the Lynn, Countisbury and the Foreland, the Tors, the Valley of Rocks, the village of Lynmouth, etc., are unsurpassed in any portion of the United Kingdom; whilst far in the hazy distance the white cliffs of South Wales can be discerned. Lynton boasts a good sized church (of which there is a chapel of ease at Lynmouth), also an excellent Independent chapel. There is a very good Wesleyan chapel close by at Barbrook, and an Undenominational chapel close by the Lyndale bridge. At the gate of Lynton Churchyard is the following quaint notice: "This is God's acre, sacred to Him and to the departed, whose bodies rest here. You are free to enter, but remember where you are. This is no place for common loud talking. Do not touch the flowers or shrubs. Allow no dogs to enter. Make fast the gate when you come in and pass out." The death rate of the parish is exceedingly small, having in some instances been as low as ten to eleven per thousand; and numerous evidences of the healthiness of the climate may be seen in the faces of neatly dressed inhabitants of great age, which may be met with at every turn; indeed, three-fourths of the deaths registered are infants under one year or people over sixty.

A mile and a half from Lynmouth is the far-famed Watersmeet, where the waters of the East Lynn and the Combe combine. The walk to this spot is most enchanting, leading the whole distance through the woods beside the brawling stream, whilst above on either side tower enormous hills. Here in various nooks are artists without number busy transferring to their canvas the views with which the walk abounds, indeed, so numerous are these generally near one spot that it has attained the name of "Umbrella Corner." At times the path is on a level with the stream, at others leads far above it, where only the roar of the cascades indicates its presence; but it invariably conducts one back to the water's edge before we have travelled far. From the Watersmeet the tourist can by a short climb reach the coach road, and return by that route; or on the opposite side of the river can find a path which will lead him over the common to Countisbury, and down the Minehead coach road on the face of the cliffs. If a good walker he may continue still farther through these charming woods, gathering wild strawberries, raspberries, and wortleberries, without number, or making bouquets of honeysuckle and wild flowers, until the village of Brendon is reached, where a rustic bridge crosses the stream at Rock Ford, and a pleasant walk through real Devonshire lanes will bring you back to your destination. Vegetation is everywhere most luxuriant, and wild fruit, flowers, and ferns in every variety attain great size and perfection. What better employment for a summer day can be found than to climb by easy stages Summer House Hill or the Foreland, where the breeze from the sea tempers the heat of the sun, and to lie in luxurious idleness and gaze upon the endless views which land and water present? Then, again, there is the Valley of Rocks behind Lynton. This can be reached by a cliff path, known as the North Walk, situate about midway between the sea and the summit of the hills, and as you walk along it seems as if the towering crags above you must topple over and carry you bodily down the precipitous descent to the sea below. After rounding one or two small headlands you come in sight of the Castle Rock, an immense pile rising from the shore in perpendicular manner, and crowned at the top with masses of stone not unlike the battlements of a castle. Turning to the left just before reaching this pile, the visitor finds himself in the Valley of Rocks. The whole of one side of this wonderful valley is formed of detached masses of rock piled in endless confusion as if to form a sort of backing to prevent the cliffs on the shore from falling inland, whilst the opposite hill (with the exception of one group of rocks called the "Devil's Cheese Wring"), is entirely devoid of stone, and rises in a majestic sweep, covered entirely with bracken and gorse. To see this place to advantage it should be visited in the evening after sunset. Then, after suddenly leaving the cliff walk

[1] Since the above was penned, public attention has been called to this fact in correspondence which has appeared in the *Standard* upon a subject relating to Lynmouth.

with its scores of gulls screaming below and around you, the awful stillness of the desolate valley has a wonderful effect. Speaking of this Valley, "John Ridd" the hero of Blackmore's charming work "Lorna Doone" says: "But all the middle of this valley was a place to rest in, and think that troubles were not, if we would not make them. To know the sea outside the hills, but never to behold it; only by the sound of waves to pity sailors labouring. Then to watch the sheltered sun, coming warmly round the turn, like a guest expected, full of gentle glow and gladness, casting shadow far away as a thing to hug itself, and awakening life from dew and hope from every spreading bud. And then to fall asleep, and dream that the fern was all asparagus."

The return to civilisation may be effected by walking back through the valley and by a lane leading to Lynton, round the foot of Hollarday Hill. If, however, it is broad daylight and you are inclined to see more, follow the road through the valley in the opposite direction and you will pass Wringcliffe Cove (a pleasant nook under the Castle Rock), and further on Ley Abbey with its picturesque walks and grounds. Further along on the shore are Ley Bay and Wooda Bay, delightful spots for picnics, or striking inland we can climb through the woods to Martinhoe Common and passing across the same, dip down on the other side by a most precipitous hill to Heddonsmouth—a romantic gorge separating two headlands, between which a brawling stream finds its way to the sea—by which time rest and refreshment at the quaint and comfortable "Hunters' Inn" will be welcomed. Afterwards we may stroll along by a footpath close by the stream until we reach the village of Parracombe, and catch one of the evening coaches back to our hotel, or return on foot by the cliffs.

Then there is the Doone Valley made famous by "Lorna Doone," above mentioned (which by the way, every visitor to Devonshire should read), but as this lies some distance away, and as walking on Exmoor is heavy work, not to mention the chance of losing one's self, it is better to take one of the various carriages which can be obtained on reasonable terms, and if you only know enough of the Devonshire dialect to keep up or understand a conversation, the driver will be glad to regale you with many a tale and anecdote relating to the various spots through which the carriage passes, and will point out Plover Barrows Farm, where lived "girt Jan Ridd;" Oare Church, the last resting-place of the same celebrity; Badgeworthy Woods (pronounced Badgery), and many other interesting localities. Near to the Doone Valley is the curious Water Slide, which in the work referred to is described as follows: "For lo! I stood at the foot of a long pale slide of water, coming smoothly to me without any break or hindrance for a hundred yards or more, and fenced on either side with cliff, sheer and straight and shining. The water neither ran nor fell, nor leaped with any spouting, but made one even slope of it as if it had been combed or planed, and looking like a plank of deal laid down a deep black staircase."

Another charming drive is to Glenthorne, the seat of the Lord of the Manor, through whose beautiful grounds you are at liberty to roam at will, or to Culbone with its tiny church (dimensions, thirty feet by twelve), situated in a glen so deep that for three months in the year the sun is never seen. Rare ferns are to be found here. Further on are Porlock Weir and Porlock town both well worth a visit. Personally the writer prefers to roam on foot through the glens and combes with which the coast abounds, and no restrictions are ever placed upon visitors who can pass wherever they like without the slightest interference, and there is always a respectful answer to enquiry made at any out-of-the-way dwelling that may be stumbled across, together with the offer of a drink of cider or milk if the day be hot. It often happens that one may walk for hours without seeing any human being, the only living things being the hardy Exmoor sheep, of which there is always a plentiful supply. It is wonderful to see these agile animals, scared by the sudden approach of man whose footstep is silent in the carpet-like turf, bound from rock to rock on the sides of cliffs which look not to have sufficient foothold for a mouse. Still, very few sheep are lost by falling over, especially in the summer season when the foothold is not so treacherous as when storms and landslips have undermined the tracks. Wherever you go or whichever way you turn views of surpassing loveliness meet the eye, and the magnitude of the hills and solitude of the glens have a wonderful effect upon one accustomed to a busy town life, whilst the bracing air either of the cliffs or moors will make you do full justice to the dainty dishes prepared for your discussion, the quality of which will not be despised by the most fastidious. There is excellent sea fishing in Lynmouth bay, where, after a day's pleasure you can lie and smoke a fragrant weed and catch your morning's breakfast; trout fishing in the Lynn, and also stag hunting within easy distance, for those who have a good seat and a better nerve.

I had almost omitted to mention the grounds of Glenlyn, which is one of the very few places in the neighbourhood where a small charge is made for admission, but taking into consideration the fact, that the money so collected is at Xmas distributed to the poor, the visitor will not begrudge a small fee for the privilege of being allowed to enter, as amongst the various enchanting spots on all sides this certainly bears the palm. The West Lynn which flows through these grounds falls 400 feet within a quarter of a mile, in a succession of continuous beautiful cataracts, over the immense rocks that crowd its romantic gorge.

As will be seen from the foregoing, Lynmouth is *par excellence* the place for a holiday. With a climate as mild and a position as sheltered as Ventnor—a good drainage system and a plentiful and pure supply of water—it is suitable for invalids, the climate being mild without being relaxing, whilst for those of stronger mould who can climb the bracing hills the place offers a never failing source of health and amusement. Dear old Lynmouth with its civil and hospitable inhabitants, it is always with a feeling of regret that we leave it to return to the sterner realities of daily routine. No one can say he is acquainted with the beauties of his native country in their best guise until he has visited this glorious spot. I may perhaps be excused for borrowing a stanza from a short poem found in a local guide as a fitting finish to this little article in which I feel I have only partially succeeded in describing a few of the features of this locality. To all who would find a place for a typical holiday resort I would say:

Come away to the mountains! 'tis good thus to roam,
Leave cankering care with your ledgers at home;
Then rest by the Lynns, with loveliness rife,
And gather fresh strength for the battle of life.

XXXIX.—FOLKESTONE.

By Charles Egerton Fitzgerald, F.R.C.S.

In considering the claims of any place to rank as a health resort, one has to bear in mind its situation, soil, equability of climate, duration of sunshine, and quantity of rainfall. Folkestone is unusually favoured as to its *situation*, having a sunny south-east and south aspect, and, lying as it does on a slight projection of the coast, is open to the fresh breezes blowing either up or down the Channel. Being built almost entirely on the cliff it escapes many disagreeables to which sea-places on a lower are subject; such as the encroachment of the sea at high tides or during gales on the basements of houses and roads lying at low level, the smell of sea-weed thrown up on the beach by a rough sea, and also the noise of the surf on a stormy night, which often becomes intolerable to a wakeful restless invalid who happens to be in a house near to the sea level. In addition to these *negative* advantages, Folkestone has the *positive* one of being comparatively above the sea fogs which seem to be such an increasing evil on all our coasts.

Besides its admirable coast situation, Folkestone is most healthily placed on its landward side, having a range of high chalk downs lying some two miles back from the town, and screening it to a great extent from the cold north winds, while their distance is sufficiently great to admit of a thorough free circulation of air between them and the sea. For all invalids suffering from nervous complaints or recovering from long illnesses, and for many pulmonary affections where a pure and bracing, but not too keen, air is recommended: I know of no place which so effectually combines all these requirements as our own town of Folkestone. It stands to reason that when, from any cause, the capacity of the lungs is diminished; the inspired air should make up in quality and in pureness what it lacks in quantity; hence the advantage of high mountain places such as Davos Platz, or pure sea air resorts, such as Folkestone, in the treatment of pulmonary complaints. The day has long passed when warm and enervating places were considered the only suitable winter resorts for invalids; it is obvious that a low-lying, cliff-surrounded place cannot have the same invigorating effect upon a weakened system as a place like this, which is open to the fresh breezes circulating between the open sea and our downs.

The soil of Folkestone is greensand, with the chalk range at the back, and this formation is one great cause of the healthiness of the place. Greensand being a very porous stratum, absorbs the rain-fall immediately, so that we have an entire absence of fog, damp, and mist, which are inevitable with a heavier soil which allows water to lodge. So porous indeed is the soil, that within a short time after heavy rain the roads are dry and clean, and pleasant for walking. The porosity of the soil is also a great safeguard in case of accidental leakage from drain pipes.

The climate of Folkestone is remarkably equable, being neither so hot in summer nor so cold in winter as many other of our watering places. To a certain extent *all* sea-side towns enjoy a more even temperature than those inland, owing to the temperature of the sea being more even than that of the earth; the sea being relatively cooler in summer and warmer in winter than the air. Folkestone being exposed on its south and south-east sides to the sea, enjoys in consequence a more even temperature all the year round than other less favoured places.

The Isotherm, or "lines of equal temperature," for the winter months are drawn from Plymouth, through Taunton, Winchester, and Canterbury to Folkestone, the mean daily temperature averaging from 45 deg. to 53 deg. The Isotherms in the interior of England are drawn from Blackburn, through Oxford, to London—from Liverpool to Hull—and from London to Flamboro' Head, and range from 40 deg. to 50 deg., showing a very considerable difference, both as to the relative mean temperature and as to its variations. In the summer months of June to September, the south coast Isotherms range only from 59 deg. to 63 deg., while those for the Midlands range from 58 to 64 deg. This bears out what I have previously stated, that on the sea coast we are relatively cooler in summer and warmer in winter than at inland places. I will give the temperature for the six winter months of a room without fire, the thermometer being by an open window and in a fairly exposed situation, the time of reading being daily at 2 p.m. I consider this a better test of the climate an invalid would experience in a winter sojourn here than that of the temperature of the open air which, however, may be taken as an average at three or four degrees below the figures I quote. Thermometer in room:—

1888.	Max.	Min.	Average.
October	67 deg.	55 deg.	62 deg.
November	63 deg.	50 deg.	58 deg.
December	60 deg.	47 deg.	54 deg.
1889.			
January	55 deg.	47 deg.	51.5 deg.
February	56 deg.	47 deg.	54 deg.
March	57 deg.	46 deg.	52.5 deg.

I think that few places could show an equally even temperature for the six winter months of our proverbially inconstant climate, there being between the maximum and minimum but

Twelve degrees in October,
Thirteen degrees in November and December,
Eight degrees in January,
Nine degrees in February, and
Eleven degrees in March.

During the six winter months, the sun shone on 105 days out of the total 182 days, being a percentage of 57 sunny days.

There is at Folkestone a sufficient rainfall, but seldom to any excess, the amount being decidedly below the average of other places. It is a very rare thing, even in the winter time, to have a wholly wet day, or one which compels the irksome necessity to an invalid of a whole day indoors. Rain fell in the six winter months on 53 days out of the total of 182 days. I will give the number of days on which rain fell, both in London and Folkestone, the latter place showing up well in comparison:—

		Folkestone	London
Rain fell in	October, 1888,	on 5 days;	in London 6 days.
,, ,,	November ,,	,, 9 ,,	,, 18 ,,
,, ,,	December ,,	,, 9 ,,	,, 10 ,,
,, ,,	January, 1889	,, 11 ,,	,, 12 ,,
,, ,,	February ,,	,, 11 ,,	,, 19 ,,
,, ,,	March ,,	,, 8 ,,	,, 14 ,,
		Total, in Folkestone, 53	In London 79

Shewing a percentage of rainy days as against London:

In October,	in Folkestone, of	16.1 per cent.;	in London of 19.3 per cent.
In November	,,	30.0 ,,	,, 67.8 ,,
In December	,,	29.0 ,,	,, 45.1 ,,
In January	,,	36.2 ,,	,, 39.3 ,,
In February	,,	39.2 ,,	,, 67.8 ,,
In March	,,	26.0 ,,	,, 45.1 ,,

The total percentage of rainy days in the said six months being 29.1 per cent. in Folkestone, and 43.4 in London, and an average of 8.8 rainy days per month in Folkestone, and 14.1 per month in London. I will also give the number of days on which rain fell in the same six months at various places in England:—

		Percentage in the six months.	Average in one month.
Rain fell at Folkestone on	53 days	29.1 per cent.	8.8
,, London	79 ,,	43.4 ,,	13.1
,, Barnstaple	79 ,,	43.4 ,,	13.1
,, Bath	83 ,,	45.6 ,,	13.8
,, Carlisle	89 ,,	48.9 ,,	14.8
,, Bradford	89 ,,	48.9 ,,	14.8
,, Eastbourne	98 ,,	53.8 ,,	16.5
,, Plymouth	102 ,,	56.0 ,,	17.0
,, Torquay	104 ,,	57.1 ,,	17.3
,, Isle of Wight	104 ,,	57.1 ,,	17.3
,, Llandudno	108 ,,	59.3 ,,	18.0
,, Liverpool	111 ,,	60.9 ,,	18.5
,, Truro	115 ,,	63.1 ,,	19.1
,, Salisbury	121 ,,	66.4 ,,	20.1

I have purposely refrained from entering on the question of the drainage of Folkestone, because I was sure it would be ably dealt with by my old friend, Mr. Bateman. Suffice it to say that, according to our present lights, it is all it should be, and is carried out on the most modern system, to which our advantages of soil and position admirably lend themselves. Air disconnection and perfect ventilation of house drains and pipes is very general. Some years ago I designed a system of street drain ventilation, through the columns of the street lamps, and proposed its adoption here, but although favourably commented on by the *Times* and by several practical engineers, our local authorities declined to entertain the idea.

The Folkestone water is excellent, and is supplied from waterworks some two or three miles out of the town, and situated on the side of the Downs, so that all risk of contamination of the water at its source is impossible. There is now a constant supply to the houses, and larger works at the same place are in course of construction to supply the needs of our rapidly increasing town. The water itself is unusually pure, the greensand whence it partly springs serving to temper the hardness of the pure chalk water.

No better proof of the excellent sanitary condition of Folkestone can be adduced than a record of dry statistics as to its death-rate, compared with that of some other towns, which are all more or less health resorts. The returns in the last Blue Book issued for 1887 are as follows:

Writing in 1871, Mr. Stainer showed Folkestone to have been for ten years at the head of the list of all watering places, with a death-rate of 16.1. There are now several other places with a lower death-rate than ours, but I will for the sake of comparison only quote those whose death-rate is higher than our own. It must not be supposed, however, that our death-rate has increased, but only that those of some other towns have diminished.

DEATH-RATE FOR 1887.

Folkestone	17.77 per 1,000.
Dover	17.94 ,,
Margate	18.27 ,,
Herne Bay	18.34 ,,
Brighton	18.57 ,,
Aberystwith	18.59 ,,
Lowestoft	18.60 ,,
Cheltenham	18.64 ,,
Hastings	18.81 ,,
Llandudno and Conway	18.83 ,,
Worthing	19.35 ,,
Ilfracombe	19.53 per 1,000.
Scarborough	19.56 ,,
Barmouth	19.90 ,,
Harrogate	20.93 ,,
Yarmouth	22.17 ,,
Cromer	23.36 ,,
Penzance	24.51 ,,

I will also give the death-rate per 1,000, from the quarterly returns for the twelve months ending June 30th, 1888. Death-rate from June 30th, 1888, to June 30th, 1889.

Folkestone	16.57 per 1,000.
Scarborough	16.58 ,,
Herne Bay	16.61 ,,
Hastings	16.69 ,,
Ramsgate	16.77 ,,
Weymouth	16.78 ,,
Eastbourne	16.95 ,,
Barmouth	17.05 ,,
Penzance	17.15 ,,
Harrogate	17.18 ,,
Whitby	17.25 ,,
Bath	17.54 ,,
Cheltenham	17.67 ,,
Leamington	18.33 ,,
Lowestoft	18.45 ,,
Cromer	19.35 ,,
Yarmouth	20.53 ,,
Buxton	24.83 ,,

PERCENTAGE OF DEATHS IN 1887.

Places with a less death-rate than Folkestone:

Ryde	14.03
Torquay	14.33
Tunbridge Wells	14.42
Buxton	15.16
Isle of Wight	15.87
Tenby	16.04
Leamington	16.38
Eastbourne	16.46
Bath	16.43
Weymouth	16.84
Ramsgate	17.45
Whitby	17.48

Folkestone..... 17.77, etc., etc.

PERCENTAGE OF DEATHS FROM JULY 1ST, 1888, TO JUNE 30TH, 1889.

Places with a less death-rate than Folkestone:

Ryde	13.60
Tenby	14.40
Ilfracombe	14.58
Dover	14.80
Isle of Wight	14.91
Torquay	14.96
Worthing	15.16
Margate	15.80
Conway and Llandudno	16.02
Tunbridge Wells	16.08
Aberystwith	16.27
Brighton	16.49

Folkestone..... 16.57, etc., etc.

It is also a fact worthy of notice that in the "Returns" for the said twelve months, ending June 30th, 1889, that there was *not one* death in Folkestone from either small-pox or measles—only three from fever, and one from scarlet fever, and for which, not improbably, we were indebted to some fever patient who came down here for convalescence, and unwittingly brought the infection either in his own person or in his belongings. In cases of infectious disease appearing among us, we have frequently been able to trace it to some non-resident who has directly or indirectly communicated it to others. That indeed is a danger to which all health resorts are peculiarly liable, although, fortunately, that danger has been con-

siderably minimised by the ever-increasing knowledge and use of disinfectants.

To turn now to the construction of the dwelling-houses, which is an important point of sanitation, and one which materially affects the comfort and well-being of our visitors, certainly in this respect Folkestone can compare favourably with many older towns. Its houses are well-planned, well-built, and well-ventilated; and, unlike most watering places, where the eye grows wearied with the dull monotony of endless terraces, the Folkestone houses are mostly detached or semi-detached, each having a brightly planted garden of its own. This forms a pleasant outlook for those who, from ill-health, have to remain much in-doors. The absence of long terraces has an actual sanitary advantage, as it allows of a free access of air and sunshine all round the houses. The trees planted along most of our roads and avenues not only add greatly to their picturesqueness, but are valuable sanitary agents in oxygenating and purifying the air.

The noted Folkestone Lees are a unique and charming feature of the place, and owing to the even level of the ground are a great boon to those who can walk but little; while the bright green of the grass, contrasting with the deep blue of both sea and sky, are continual refreshment and pleasure to those who come, wearied in mind and body, to be restored to health and strength by our life-giving sea breezes. There is hardly a day in the winter season when a sunny walk may not be taken on the Lees and cliffs; and to many invalids who dread the fatigue of a long journey to warmer climes, the sheltered paths in the cliff, open to the full blaze of the noon-day sun, and screened from the cold inland winds, offer all the advantages of the Riviera, without fear of its treacherous mistral.

I have dwelt specially on the fact of Folkestone being built almost entirely on cliffs, as the greater proportion of the houses where our visitors stay are on the cliff; still for those who prefer a more sheltered situation, the houses on the lower parade, under the cliff, are admirably adapted and are equally well built, and as commodious as those on the cliff above. Since the erection of the hydraulic lift, all difficulty of transit between the upper and lower parades has been abolished, a few seconds sufficing for the journey between the new Promenade Pier and the Lees.

The sea at Folkestone is remarkable clear, owing to the shore being pebbly rather than sandy, and the sea bathing is excellent; new and well arranged bathing houses, with a sliding action on rails, having to some extent superseded the older bathing machines; they are also fitted with a platform for diving. There is besides a good "Bathing Establishment" fitted with hot and cold sea and fresh water baths, a large swiming bath, and all kinds of medical baths, under the supervision of trained attendants.

The country around Folkestone is varied and picturesque, and there are many charming walks and drives for those who can take them; while for those whose health precludes them from taking more exercise than the mild luxury of a bathchair, the long asphalted walk on the Lees offers a delightfully smooth and level path, far superior to the gravelled parades and flagged pavements of other sea-side towns.

For the younger and more athletic of our visitors, there are plenty of healthful amusements, such as riding, cricket, and tennis, nearly every house having the use of some tennis ground; and for those who are "golfers," we have capital links with a course of three miles within half a mile of the town. The boating is also good, and there are facilities for excursions to the Continent, owing to the service of steamers which cross daily between here and Boulogne.

The Warren, too, is a source of endless joy to the Naturalist and Geologist, from the variety and beauty of its flora and fauna, and the richness of its strata. I may mention here that we have an excellent "Natural History Society," numbering over a hundred members—also a good Museum and Free Library. I have not touched on the subject of entertainments, as they are not, as a rule, considered a necessity to the health seeker; still, for the benefit of those who are able to enjoy the pleasures of life, I may add that we are no way behind other towns in our concerts and our theatricals—our regattas and our polo matches—our military bands and military tournaments.

Some may think I have dwelt unduly on the numerous amusements and attractions of Folkestone, but there can be no doubt that rational amusement conduces largely to health, both of mind and body, and is a real physiological stimulant and restorative, often far more potent than medicine. The recent researches of Bouchard on the animal alkaloids, the ptomaines, and leucomaines, generated in the human body, and which produce so depressing an effect on the health and spirits, tend to show that these poisonous alkaloids may be profoundly modified in their formation by just that condition of exhilaration of the nerve centres, which results from healthful amusement. Pleasure may thus exercise a physiological and chemical as well as physical effect.

If this theory be true, it points to the conclusions that, although in every health resort, sanitary surroundings should be the first consideration, yet no place, however great its advantages, can afford to neglect the rational entertainment of its visitors, for cheerfulness is scarcely less a physiological necessity than a pure sanitation.

THE FUNCTION OF THE SEMI-CIRCULAR CANALS.

By G. Cadogan-Masterman, M.D.

A lecture of unusual interest was recently delivered in Dundee, by Professor Crum Brown, on "Our Sensation of Motion," and especially on the means we possess for the estimation of gestation, passive translation, without any muscular effort of our own. And he showed, as an introductory paradox, that we have, apart from the evidence of visual impressions, no means of estimating it whatever. For example, we know from the teaching of astronomy that we are moving through space at the rate of 68,000 miles an hour, but, were it not for that knowledge, we could not possibly be aware of it, and practically it is utterly inappreciable. And on a smaller scale, and at an enormously less speed, steady motion without change of orientation, is as little felt by us. When travelling by railway on a straight, well-laid section, except for the slight bumping due to the imperfect rail joints, if we keep our eyes shut by day, and during a dark night, we have no sensation of our onward progress; if the carriage could be kept *in situ* and slightly oscillated, we might imagine that we were still travelling with undiminished speed.

This is true, however, only so long as the motion is continued in a sensibly right line and with uniform speed. The moment a change is made in either respect, we become conscious of a something, some change of state, which we

at once recognise, and yet, unless we have reasoned it out, find hard to define. We find it when starting, when beginning to ascend or descend a steep gradient, when passing round a sharp curve, and especially when speed is suddenly slackened. A person who experiences for the first time the action of the continuous brake, is aware of it with very disagreeable distinctness, and the sensation is curiously like that which the unaccustomed sailor feels when a ship is plunging far down the awesome slope of an Atlantic wave.

And this does not apply only to change of place approximately horizontal, but in vertical direction also; when ascending and descending in a well-managed lift, we feel for a fraction of a second only that we are being moved, and, again, that the transition is being arrested; in mid passage we might be standing on the unmoved floor as far as our sensations can inform us. And in the car of a balloon it is the earth which seems to rush from beneath us, the summer clouds are as motionless as we fancy we are ourselves.

The sensation of passing round a sharp curve is that of partial rotation; when that rotation is complete and repeated, the sickening feeling of vertigo is quickly induced, some people, especially when the arteries are losing their elasticity, cannot even turn their head quickly without experiencing it. But Professor Mach, of Jena, to whom we are indebted for the original and most painstaking investigation of this subject, shows that rotation can be performed with impunity, and unfelt—except at the moment of its commencement or cessation—if all visual impressions be effectually excluded. This can be done either by careful blindfolding or by placing the subject of experiment in a little hut on the revolving table, with paper windows on which no shadow or changing light is allowed to fall. At the instant of starting, the sensation of motion is evident, but before the table has made a complete revolution it has disappeared; and so long as the table is whirling at a uniform rate, it is completely absent, returning, however, whenever the speed is changed or when the rotation ceases. And this is equally true whether one be sitting in a chair or lying down.

Now, what is the mechanical effect upon the trunk when motion is imparted to the whole of the partially supported body? We know that if we be sitting upright "with our face to the horses," when a train starts the head is thrown backwards, and in the same way it is projected forwards when the train is stopped, in obedience, of course, to Newton's first law of motion; and if the head be resting against the back of the carriage in the first case, we still have the *sensation*, although the real movement is practically *nil*—and that sensation, when reduced to a single term, is the appreciation of a change in perpendicularity.

It might be objected that the feeling is referable to the point of support—the feet or the buttocks; but it is felt as clearly whilst one is in the water, where the body has no weight, and is on all sides equally supported; and that this is not so is best demonstrated on the revolving table. Let the experimentor sit with his head reclining so that one ear is uppermost when the table is set spinning; at the first movement the motion is felt, and then disappears. Let him now raise his head suddenly, and there is instantly a vivid feeling that he is falling out of the chair in the opposite direction to the movement of the head, and a violent instinctive effort will be made to prevent it, which may result in a falling out of it in reality; in fact whenever the experiment is made for the first time, the subject should be strapped in the chair to prevent accident. And it is still better shown in lying down on the table. Let the experimentor lie on his side, with the head comfortably raised on a pillow: he is revolving with the table, but feels as if he were reclining on a motionless couch. Then let him suddenly turn on his back, and he experiences the most horrible sensation of his bed having become vertical, and that he is falling in space! He clutches madly at anything within reach, and with difficulty realizes that he is still resting in perfect safety, and that he and not the couch has changed position.

This sense of personal perpendicularity, that is of the position which the head occupies in relation to the feet, is only vividly present to us when it is being disturbed, and is intuitive; a man may be sitting in a stooping position unconsciously, but it is hardly possible to change that position without the alteration being clearly estimated in time and angularity. It is evident, therefore, that we are furnished with some organ which accurately measures both, and Professor Mach believes that it is to be found in the semicircular canals.

The view of physiologists has hitherto been that this singular apparatus is part of the organ of hearing—which its position naturally suggests—and that its special function is the appreciation of the direction of sound. But if this were true no part of our organism could be said to do its work so badly; there is nothing of which we have such imperfect knowledge as the position of a source of sound if we have to trust to our hearing only to supply it; it is only by a process of observation or unconscious reasoning that we can assure ourselves of the locality. The tricks of the ventriloquist are the clumsiest, but the most successful which impose upon our senses.

Yet the semicircular canals are clearly intended for measuring something in three planes, or as a trigonometrical instrument for estimating some change in space, and the latter we have every reason to believe is their true function. There are three tunnels, excavated in bone of considerable density, almost circular in section, somewhat more than half a circle in extent, and placed approximately at right angles to each other. For the greater part of their length their diameter is uniform, but one extremity of each is dilated to form its ampulla, and they communicate by five openings (the two vertical tubes having one in common), with the vestibule at each end. They are occupied but not filled by membranous tubes of the same form but less diameter, and each of the three bulbs is firmly attached to the edge of the opening it adjoins, whilst the rest of the tube floats free in the pellucid perilymph which surrounds it, a similar fluid—the endolymph—keeping the tubes distended. The tubes have, then, limited motion in one direction—away from the mouth of the ampulla—and its effect is to elongate them; and any force causing this, acts in an opposite direction on the corresponding tubes on the opposed sides of the head. The nerves are distributed to the ampullæ, and end in hair-like filaments, with minute particles of carbonate of lime between them. We may imagine, then, that force travelling in the same plane as either tube, and away from the bulb, would tend to elongate the ampulla, and to convey a certain impression to the nerve-cells within it; but only when the bony wall was not impressed by the same force, for, if both moved together, no change in form or position could take place.

We have, therefore, the conditions for estimating impulse, but not continuous motion; change, but not permanence in position. And this accounts for the fact that we feel the motion of the most perfect carriage when it is starting or stopping, but not when it is travelling steadily in the same direction. Any change of speed, any deflection, disturbs, however, the equilibrium for a moment of the tube floating in one of the canals, and then we not only feel the change, but are aware of the direction in which it has been made.

Prof. Mach believes, also, that the function of the otoliths in the ventricle and saccule is the estimation of horizontality; these little groups of lime crystals lie in a bed of jelly on the *macula acoustica*, which is pierced by hair nerve-cells, and placed, when we are upright, in the same plane as the earth's surface; deviation of the head from the vertical would tend to make the otoliths press unequally against the nerve-cells, and a sensation of that change would be sent to the brain.

Prof. Crum Brown shewed experimentally that such an arrangement would act in accordance with the theory. In an open frame two heavy horizontal wheels were pivotted; they could move slightly only in one direction, a stop preventing their rotation in the other, and a spiral spring keeping them in contact with the stop. The frame carrying the wheels could be revolved at will, and it was seen on doing so that one spiral spring was elongated at starting, and that on the other wheel in stopping, but that when the frame was rotating smoothly neither spring was affected. This was made evident to the audience by the elongating spring widely opening a tap in a pipe leading to a gas jet, and nearly closing it as it recoiled and remained inactive. For a few spectators I should suggest placing two spirit-levels on the opposite sides of a heavy horizontal wooden wheel which could be rotated or stopped by a hand, and the movements of the air bubbles would show the same phenomena very clearly and simply.

THERAPEUTICAL NOTES.

From our Berlin Correspondent.

Details on Chloralamid, the new Hypnotic—Phenacetin and Caffein combined for Migraine—Treatment of Diphtheria with Acid Corrosive Sublimate Solution—Danger of Chloroform Anæsthesia at Gaslight — The Harmlessness of Creolin.

In my last letter I had occasion to draw attention to the latest of the new hypnotics called chloralamid. Since then several publications have appeared on the subject which are all full of praise for the new remedy. It will therefore be of interest to deal somewhat more fully on the properties and effects of the substance, and I cannot do better than give your readers a brief account of the investigations of Drs. Lettow and Kny. Dr. Lettow has written a thesis entitled, "Chloralamid as a Hypnotic," approved of by the medical faculty of the University of Greifswald. He treated altogether sixteen cases with the new sleep producer, administered fifty-seven single doses, which represent a total amount of over five ounces of the drug. In three cases out of the sixteen he gave it to quite normal persons; in the other thirteen cases the object was to relieve the existing insomnia.

With regard to the causes of insomnia the thirteen cases range thus:—

Neurotic and senile insomnia	3
Alterations of the circulatory system	1
Sarcomatous cachexia	1
Neurasthenia	1
Phthisis combined with diabetes	1
Chronic rheumatic arthritis	1
Cancer of the stomach	1
Delirium tremens	2
Sciatica	1
Bronchial asthma	1

Usually forty-five grains were given at one time. In two cases (delirium tremens) the dose was forty grains; in six cases (circulatory disturbance, senile insomnia, phthisis, delirium tremens) it amounted to thirty grains, and in one case (delirium tremens) only fifteen grains. Fifteen grains were without any visible effect; forty grains acted very satisfactorily in both cases; thirteen grains sometimes produced a good sleep; in other cases the dose was evidently too small.

The total result of Lettow's experiments is to the following effect:—

(1) Chloralamid is a very efficacious and useful hypnotic, though it is no panacea for all cases of insomnia.

(2) The greatest advantage over other hypnotics consists in its having no influence whatever on pulse, respiration, and temperature.

(3) After-effects are very scarce, if occurring at all, they consist of slight headache or a trace of giddiness.

(4) The safe dose for an adult is forty-five grains.

(5) The drug is best given one to one-a-half hours before the desired sleep is intended to commence.

(6) Chloralamid when given as an enema is very reliable.

(7) The hypnotic effect is occasionally prolonged over part of the following day.

Dr. Eugen Kny, assistant physician to the clinic for mental diseases of the University of Strassburg, published in the "*Therapeutische Monatshefte*," August, 1889, the results of his extensive physiological and clinical experiments with chloralamid. He first gave the drug to a great number of animals, and observed a marked hypnotic effect in nearly all cases. After the artificially produced sleep was over, the animals felt all the better for it, and showed no unpleasant symptoms whatever. In one series of experiments the effect of the drug on the blood pressure was studied, the latter being recorded before, during, and after the administration of the drug. The result of these experiments was that chloralamid in contradistinction to chloralhydrate, with which it is in close relation, chemically as well as physiologically, does not materially alter the arterial blood-pressure; whilst chloralhydrate frequently caused a decrease of the blood-pressure to the amount of fifty to eighty m.m., chloralamid caused only seventeen m.m. reduction—*i.e.*, not more than is observed during natural sound sleep. This shows that the drug has not only no poisonous effect on the heart, but does not even effect its action in any nominal degree. Dr. Kny, after having proved the harmlessness of the new substance on animals, went a step further and tried the drug on patients. He gave it more than one hundred times in thirty-one different cases of insomnia; in some of these cases he had previously given chloral hydrate, so that he had an

opportunity of comparing the therapeutic value of the two drugs. Chloralamid had a favourable effect in all cases of insomnia caused by nervous excitation, if not accompanied with intense physical pain; furthermore, in all cases where some organic lesions, such as phthisis, heart disease, pleurisy, etc., caused the sleeplessness. Old patients with weak hearts slept very well after chloralamid, which they took without showing any unpleasant symptoms. As a rule the chloralamid sleep was deep, refreshing, and sound; its duration varied between six and ten hours. In the morning the patients woke with perfectly clear head, and without any derangement of the digestive organs. Sensation of weight in the head, general malaise and unpleasant taste in the mouth, complaints quite common after chloral hydrate sleep were, Kny states, never heard of after chloralamid. He considers that another important advantage of the latter consists in its not irritating the mucous membranes in the least. A 10 per cent. solution applied to the conjunctiva did not cause any burning sensation, whilst intense pain is felt by similar application of chloralhydrate solutions. Regarding the methods of administration, he recommends to dissolve the drug in some wine or other similar alcoholic beverage. Given in this method, even patients of very weak constitution and deranged state of digestion had no ill effects whatever from it. Besides the drug may also be administered in wafers. Kny lays particular stress on the important property of chloralamid, not to affect the heart and the general circulation of the blood. This combined with the absence of secondary effects, and the nearly complete tastelessness of the drug, form, according to Kny, the chief important advantages of chloralamid over chloral hydrate.

In concluding he recommends the hypnotic for the following cases:—Sleeplessness in consequence of nervous irritation of medium severity, neurosthenia; organic lesions, such as phthisis, heart disease, spinal affections, etc., and in all cases of insomnia not brought on by intense pain or general excitatory state of the whole nervous system.

Dr. Hammerschlag publishes in the *Allgemein Medicinische Centralzeitung* the following combination of remedies, from which he saw excellent results in the treatment of migraine.

℞ Caffein citrat..... gr. 1½
Phenacetin..... gr. 3
Sacchar. lactis..... gr. 5
S. One powder to be taken every two or three hours.

The *Berlin Klinische Wochenschift* contains an interesting article of Dr. Rennert, of Frankfort-on-the-Main, on the treatment of diphtheria with acid corrosive sublimate solution. The author used a solution of ten grains of corrosive sublimate, thirteen grains of tartaric acid, and one pint of water. A straight dressing forceps, with a pad of cotton-wool, one inch long and half an inch thick, is dipped into the solution, and swept over the pharynx from below, upward. The false membrane comes off, and the remaining slightly bleeding raw surface is disinfected by this process, which has to be repeated every six or twelve hours. One single procedure lasts from five to twenty minutes, ten to twelve pads of cotton-wool being frequently required for one single thorough disinfection. The author reports very remarkable success with this new treatment; but he distinctly stated that for obtaining really good results, energetic action, notwithstanding bleeding, vomiting, and objection of parents, is quite indispensable. During a course of fourteen months he treated sixty-two cases in the way stated above, and the result was without exception successful in all cases.

The same paper contains an article by Dr. Hobwasser on the decomposition of evaporating chloroform by the action of gas burnt in the same room where the administration of chloroform is proceeded with. Chloroform vapours thereby undergo decomposition into phosgen, hydrochloric acid, free chlorine, and a few yet unstudied substances which undoubtedly possess toxic properties. The author therefore cautions against the use of chloroform near gaslight, and recommends thorough ventilation of every operation, theatre, or other rooms where chloroform is being given.

An interesting case of creolin poisoning happened the other day at Berlin. A labourer, employed in a chemical factory, with the intent to commit suicide, swallowed not less than eight ounces of creolin. Dr. von Ackeren, who published a detailed report on the case, observed only very slight and passing symptoms of poisoning, whilst the patient perfectly recovered. The fact that a dose of eight ounces was not sufficiently toxical speaks greatly in favour of creolin, which, though a powerful disinfectant, is comparatively harmless to the human organism. If we consider that the tenth part of carbolic acid would have proved fatal to the man, we cannot deny that it is of great advantage to possess non-poisonous antiseptics like creolin.

Reviews.

The Diseases of Children, Medical and Surgical, by Henry Ashby, M.D. Lond., M.R.C.P., Physician to the General Hospital for Sick Children, Manchester, etc.; and G. A. Wright, B.A., M.B. Oxon., F.R.C.S. Eng., Assistant-Surgeon to the Manchester Royal Infirmary, and Surgeon to the Children's Hospital. London: Longmans, Green and Co. 1889.

[Concluding Notice.]

Tuberculosis comes first among the general diseases; here it is remarked that tubercular affections in children are not so limited to the lungs as in adults, but are more widely distributed through the body, and that the stress of such lesions is first in the chest, next in the abdominal organs, then on the head, and, in the last stages, on the membranes of the brain. It is noted, p. 297, that miliary tubercles in the choroid may be an early sign in acute tuberculosis. Further on (p. 299) we find "that all scrofulous or strumous lesions are identical with tuberculosis;" and the following:—"In certain children there is a characteristic tendency to inflammation from trivial causes; this inflammation is specially apt to occur in, or rather pick out the lymphatic tissues; once aroused, it tends to spread, attacking often distant parts of the body. If its course is slow the foci of disease tend to become caseous; once started, the process seldom stops, or rather, though it may be arrested for a time, it is apt to be set going again by slight causes, even after long intervals of time. This tendency is found to run in families, some members showing one form of lesion, some another." The surgery of the lymphatic glands is well given. That of tubercular bones and joints is found from pp. 509 to 572. We quote from p. 512:—"The usual history of a case of chronic

tubercular synovitis of the knee-joint in a child is as follows. There is perhaps a history of phthisis or joint disease in the family; the child has been healthy, till at the age of, say, four years it was attacked by measles or some other exanthem. It was slow in recovery, and was never quite strong afterwards; a year later perhaps, it received some injury to the knee. Shortly after the knee swelled, but gave rise to no great pain or inconvenience, except a slight limping and feeling of tiredness; the swelling slowly increased and become somewhat more painful, especially at night, with night startings." A foot-note strongly insists upon the fact that tubercular disease of joints may go on for months, getting worse, without pain and but little impairment of mobility. This might have formed part of the text. Sometimes a note is used for supplementary facts; thus, to the statement that of 125 cases of joint disease only six were consecutive to measles, four to scarlet fever, two to typhoid, and three to whooping-cough, is a note that of 192 joint affections, in forty-three there was a tubercular family history, in sixty-one the disease had followed an injury, and that in nineteen patients the tubercular lesions were multiple. We notice, chiefly in the surgical pages, more than fifty such additions, many of which might well have come into the body of the work, even at the sacrifice of some wood-cuts to make room for the larger type.

In the five chapters on "Diseases of the Nervous System," both authors are seen at their best. The opening remarks on Meningitis, and the section on *Diagnosis*, afford much that with difficulty we refrain from quoting, and must be content simply to commend. After Chorea come sections on Epilepsy, Eclampsia, Hysteria, Headaches. Here we read:—"In sensory hysterical disorders, such as headaches, and in various forms of paralysis, the question is whether or not there is cerebral tumour or spinal disease. Probably the commonest mistake is to assume that organic disease exists when the condition is one of hysteria only; . . . it is always necessary to bear in mind that an organic lesion may exist and yet undoubted hysterical symptoms be present" (p. 418). In these chapters infantile paralysis or anterior polyo-myelitis, essentially a spinal disease, is separated from infantile hemiplegia and spastic paraplegia; but in chapter xxii. it is remarked (p. 387) that "An *anterior polyo-myelitis* may be of hemiplegic distribution." Hemiplegia in children is mostly from embolism, and rarely from cerebral aneurism; among its other cerebral symptoms, convulsions or increased tendon-reflex are noted. In cerebral tumour it is remarked that the headache or special vomiting without optic neuritis and certain paralyses would not suffice to establish the presence of organic disease or guide to its localisation. On the surgery of this subject, and of cerebral abscess, it is said (p. 384), "At present only those growths which lie in or near the surface of the cerebrum have been successfully dealt with; tumours at the base of the brain, or involving the basal ganglia, may be looked upon as inaccessible to surgery at present, and, though cerebellar growths are not beyond our reach, but little has been done for their removal. Surgery chiefly deals with growths situated in the motor area of the cortex, since the localisation of the tumour is most satisfactorily to be made out in this region." It is further remarked that, "on the one hand, the brain in childhood is more tolerant of operation than in the adult, and on the other hand, brain lesions which prove fatal to adults are not only recovered from in children, but may leave little or no permanent effects." In cerebral abscess, where the symptoms of tumour mostly follow upon a rigor or other febrile sign, "there is little hope in any method of treatment, except operation." The frequent connection of this and other cerebral lesions with affections of the middle ear is treated of at p. 602, but no new statistics are given.

We know from Bürkner that of eleven deaths from this cause, six were owing to meningitis, three to intra-cranial abscess (two cerebral and one cerebellar), and two from pyæmia or phlebitis. Instances of ear disease after measles, scarlet fever, and small-pox, are noted—that of the latter, at p. 604, is not indexed; indeed, neither the words small-pox nor variola have a line in the index, and the short notice of so important a disease points to a want our present system of special hospitals occasions. Chapter xxvi. treats of diseases of the kidney; the causes of hæmaturia are considered, and its significance in purpura, hæmophilia, the acute fevers, calculus and malignant disease. Hæmoglobinuria occurs in children. Among styptics hamamelis is twice spoken of (pp. 312, 454), but we are glad to see a mention at the latter page that where it fails gallic acid and ergot are efficacious. The eminently practical tendency of the whole book is shown by scattered comments on medicines likely to be useful, in addition to the fifty-four formulæ embodied in the text; in one of these (No. 22) a slight typical error occurs. The appendix contains directions as to milk, barley-water, whey, meat-juice, &c.; also as to poultices, fomentations, sponging, packs, baths, ice and other anti-pyretics. Five pages are devoted to the doses and usage of medicines and of stimulants; directions for forced feeding and the use of disinfectants come at the end. The great utility of this summary is obvious; we have but one omission to note—viz., that of castor oil, from the list of purgatives and laxatives. Castor oil should come at the head of the list, and a formula for an emulsion of it, as in use at most London hospitals, might have been given, such as No. 6, p. 64, or for a similar mixture made with hot water and sugar at home. Some exception may also be taken to the prominence given to grey powder and calomel; that the former is very frequently misused is not in itself a warrant for the continuance of the practice. We find both these drugs often, and antimony sometimes, ordered to be repeated indefinitely, as in Nos. 19 and 22A, and in ailments so frequently associated with rickets or tuberculosis that a caution is needed. The use of euonymin, antifebrin, pyrodine, hyoscyamine or hyoscine, is doubtful; but a free trial of new remedies, and free use of the old, may be thought favourable to therapeutic progress.

The intimate connection of the medical or surgical parts of the work under review has been here shown by extracts so numerous that less than a due share of comment and approval falls to the lot of the purely surgical subjects. On going through the surgical chapters their importance in repairing the results of disease are seen at a glance, and, in our judgment, the details are admirable. Both authors are to be congratulated on the achievement of a great success. We now have a complete work on the diseases of children, combining the excellencies of West with the specialities of Cooper, Forster, and Edmund Owen, but founded on original observations and the joint experiences of two men of great fitness and ability for the task, who are ready to judge of facts as they come before them, and who work together with the best practical results.

If the true function of criticism be, as it has been defined to be by no less a master of the art than the late Matthew

Arnold,—"A disinterested endeavour to learn and propagate the best that is known and thought in the world," we claim to have learned much from the book before us to add to what was already known, and to have done our best to make this source of knowledge widely available.

[In our last number an intended correction at the commencement of p. 540 is put as part of the text, and so the point missed that a cavity is *evacuated*, and the contained fluid *let out*.]

The Human Foot: its Form and Structure, Functions and Clothing. By Thomas S. Ellis, Consulting Surgeon to the General Infirmary at Gloucester. London: Churchill. 1889. 8vo., pp. 120.

It is by no means an easy task to write a review of this book. The author himself thus introduces it to his readers. "A book by a surgeon on a subject closely related to his profession, but not intended exclusively for members of it, may call for some explanation as to origin and object." The following remarks then may be assumed to furnish the suggested explanation. "The City and Guilds of the London Institute for the Advancement of Technical Education have for some years past conducted examinations in a variety of subjects: in these is included, under the head of boot and shoe making, 'The Anatomical Construction and Natural Functions of the Human Foot.' On every subject but this the names of works of reference are given, the list being often a long one, of books in English, French, and German. The want thus plainly indicated is felt by those who, in military or in civil life, or as regards either sex, desire to understand the principles of physical education, and who, knowing that the form of the body is influenced more by the manner than the amount of muscular exercise, seek to learn how to direct it. Evidence is offered that—at least in one respect—the ordinary mode of using the feet, although supported by military authority, is wrong."

Details of anatomy have, so far as possible, been avoided. Such as are necessary are given together with illustrative plates—seven in number—and explanations, which describe the bones, ligaments, tendons and muscles which contribute to form and move the feet. The two feet, the author points out, are perfectly symmetrical, while there is a marked difference between the two sides of either one, taken singly, it being of the utmost importance that those who seek to understand the mechanism of the foot should fully realise this absence of symmetry between the inner and outer side. The structure of the arch is treated of at considerable length. Mr. Ellis has also fully entered into the consideration of the analogies between the human and other mammalian lower extremities, as regard their ligaments, muscles, and bones, and the various positions and attitudes these severally assume. The functions of the feet in standing, walking, marching, etc., are treated of in relation to the make of boots and shoes. This subject is discussed in a strictly scientific spirit, and may with much advantage be studied by military authorities.

In the preceding remarks we have endeavoured to put before our readers the sum and substance of an essay which embraces a wider range of topics than would have been anticipated from its title, and from which, we are of opinion, great advantages may be reaped, both in civil and military as well as medical circles. W. B. Kesteven, M.D.

Short Notices.

Synopsis of Human Anatomy. By James K. Young, M.D. Philadelphia and London: F. A. Davis. 1889. 8vo, pp. 393.

The object of this little book is, as its title indicates, to furnish a concise, thorough, *complete synopsis* of human anatomy for the use of students of medicine and others. Appreciating, from personal contact with students, the limited time at their disposal and the unlimited amount of medical material to be digested, the author has endeavoured, by well-selected woodcuts, typographical arrangement, and numerous tables, to facilitate the acquisition of a subject as difficult as it is essential, and elegance of diction has therefore been sacrificed to conciseness and accuracy. Sufficient descriptive matter has been added in reference to the sections on the viscera, special senses, and surgical anatomy, to render this work useful to the practitioner. To the advanced student it will prove valuable as an aid to memory. We should characterise it as being a clear, concise, and compendious summary of the anatomical details, which are to be found more fully described in the larger treatises of Quain, Holden, Henle, Schaffer, Klein, and others.

W. B. Kesteven, M.D.

The Ophthalmic Review. London: Churchill.

The *Ophthalmic Review* for August contains the second lecture by Marcus Gunn "On Congenital Malformations of the Eyeball," delivered at the Great Ormond-street Hospital. He deals with affections of the eye-lids, cornea, iris retina, and choroid, concluding with an explanation of the cause of coloboma of the choroid. The same author makes a suggestion that the cause of traumatic cataract is to be sought in the action of the chloride of sodium of tne aqueous on the globulin of the lens, and further that the solution of a cataract after puncture of its anterior capsule is due to the fact that globulin is normally soluble in dilute saline solutions, like the aqueous. The rest of the number consists of reviews, an abstract of the transactions of the last meeting of the Ophthalmological Society, and a list of recent literature.

W. T. Holmes Spicer, F.R.C.S.

The Clinical Use of Prisms, and the Decentering of Lenses. By Ernest E. Maddox, M.B.

This little book treats of an important but much neglected branch of ophthalmology; partly from the inherent difficulty of the subject, and a consequent want of precise knowledge, and partly from insufficient data, prisms have not been used by surgeons to the extent which their value demands. Many of the most troublesome ocular affections, slight muscular defects, and anomalies of innervation can only be successfully treated by prisms. The author supplies in a very clear form, a guide to the properties and uses of prisms, and to the decentering and displacement of lenses; the book contains useful tables for the measurement of prisms, the analysis of spectacles, and for showing the prismatic effects of decentering lenses, obviating the necessity of recourse to mathematical formulæ. Perhaps the author aims at a greater degree of accuracy than can always be obtained in dealing with such variable quantities as muscular innervation, but this is a fault on the right side.

W. T. Holmes Spicer, F.R.C.S.

The Provincial Medical Journal,

OCTOBER, 1889.

The presidential address of Dr. Hack Tuke at the Leeds meeting of the British Medical Association is deserving of the careful attention not only of the profession, but of all interested, as ratepayers and as managers. The future provision of our lunatics is becoming an important social question, as it involves an enormous outlay, to which some check must be put, or some remedy be suggested. It is only by free discussion we can arrive at a solution, and the historical sketch given by Dr. Hack Tuke must be regarded as a *memoire pour servir* towards the settlement of this most important question.

Dr. Tuke began with a reference to the Lunatic Hospital at York, generally known as the Old York Asylum, founded in 1777, which was now an attractive institution, containing 135 patients on January 1st, of whom forty-six were paupers. Taking the estimate of Dr. (afterwards Sir William) Ellis, the proportion of pauper lunatics in 1815 to the population of the country would be one in 1,300, whereas now it was one in 560. The Wakefield Asylum was constructed to accommodate 150 patients on what was called the H plan, and was opened in November, 1818. The grave defects in the Wakefield Asylum arose from those who planned it having lived during the earliest stage of development in asylum architecture. In 1846 the population of the Wakefield Asylum reached about 450. In ten years the number advanced to close upon 800; while in 1871, just before the opening of the second West Riding Asylum at Wadsley, the highest number in the history of the institution was reached, 1,494. The number resident on the 1st January last was 1,354. The Wadsley Asylum was built to accommodate 750 to 800 patients, and was opened in August, 1872. On the 1st January last, however, it contained 1,616 patients, while the population of the Riding at the census of 1801 was about half a million, at the present time it was two and a half millions. The consequent demand for additional accommodation for pauper lunatics led to the erection of Menston Asylum, opened in October, 1888. The buildings now erected would accommodate 840 patients; and those for chronic cases, designed but not erected, another 250 or 300 of each sex, making a total of 1,440 patients. He thought it would have been wise at the present crisis in the history of county asylums if the magistrates had avoided anything in the way of costly embellishment calculated to prejudice the mind of the ratepayer on entering the building. Without the expenditure of so large a sum, the structure might have been as substantial, while cheerful surroundings could also have been still obtainable. On visiting the asylum he could not help thinking that it might very possibly be utilised some day, to a certain extent at least, as an asylum for the middle and even the upper classes, some of whom at present occupied much humbler quarters in private asylums and registered hospitals. To some of the poor labourers of the county it was probable that a more homely or more home-like dwelling would have been no less adapted to the comfort and cure of the inmates. He hoped before the remaining blocks were built consideration would be given to doing away with passages, seeing that patients residing in blocks would be of the chronic or more or less incurable classes. As to the Menston Asylum, visitors would be welcomed at any hour during the meetings. In the North Riding Asylum at York there were on the 1st January last 622 patients; in the East Riding Asylum at Beverley 291 patients; and in the Hull Borough Asylum at Cottingham there were 300 in residence. But besides these, Yorkshire had shares in the provision for the education and training of idiots and imbeciles in connection with the Royal Albert Asylum at Lancaster. Of 553 patients in that asylum 180 belonged to Yorkshire. According to the census of 1881 there were in Yorkshire 2,903 idiots and imbeciles, whether paupers or not, who were at the rate of 1 in 997 of the population; while the proportion in England and Wales was 1 in 794. As an instance of a serviceable workhouse where lunatics were treated, the President cited that at York, under the charge of Mr. S. W. North, there were 120 patients, and during the last fifteen years the annual admissions had averaged twenty-six. Of 256 discharges during the fifteen years, eighty-two were sent to their friends, thirty-seven to an asylum, and 131 died. Mr. North calculated that the saving to the ratepayers of the York Union by properly utilising the workhouse for insane paupers was not less than £1,000 a year, but no case had been kept in the workhouse to the prejudice of the patient. The number of insane in detention in Yorkshire workhouses was 1,316, or 22.26 per cent. of the total pauper lunatics in the county; while 330, or 5.58 per cent., were resident with friends or elsewhere. There were 4,265, or 72.16 per cent., in asylums; while the percentage in England and Wales was 69.01 per cent. The recovery rate in the Yorkshire asylums had been 39.69, and in England and Wales 35.57. Unfortunately, medical men were yet found endeavouring to explain the apparent increase instead of decrease of insanity. The superintendent of the Wakefield Asylum, from knowledge of the masses from which his patients were derived, was led to form a very unfavourable opinion of the mental status of many outside our asylums. Hence to the prevention no less than the cure of insanity must their future efforts be bent.

The question of future provision for pauper lunatics was treated also by the President, and in this paper there were many suggestions of great value. He discussed the question of boarding out pauper lunatics with strangers; the payment of a more liberal sum to the relatives for which workhouses ought to be utilised; the operation of the Government grant in aid of pauper patients confined in asylums; and lastly, the advisability for providing separate buildings for the acute and chronic cases. Reference was made to the experience of Dr. Mitchell, the late superintendent of the Wadsley Asylum, Dr. Major, the former, and Dr. Bevan Lewis, the present, medical director of the Wakefield

Asylum, as opposed to the boarding out of pauper lunatics with strangers. On the other hand, it was shown that the remuneration of relatives for taking charge of their insane friends works favourably. Dr. Buckworth William's experiments at Hayward's Heath was adduced to show what could be done in this direction. Evidence was afforded that the use of workhouses in Yorkshire had been resorted to with advantage. The Commissioners in Lunacy favour increased use of the workhouse for chronic cases, provided there is proper accommodation in the lunacy ward. The effect of the capitation grant in filling asylums wtth chronic cases was insisted upon. The Local Government Act and the Lunacy Act were referred to in relation to it. In regard to asylums, the buildings for acute cases should be distinct, although in close relationship with the central establishment, and be more expensively built than the blocks for chronic patients. Hospital arrangements for the sick and acute were advocated, but too much had been expected from medical treatment of recent cases, a large proportion of patients brought to asylums being incurable, even when recent. The discussion which followed was a very useful one, as it was joined in by men of great experience and sound judgment.

Dr. Ringrose Atkins (Waterford) thought boarding out could be carried on in Ireland under a colonisation system. In that country the workhouse authorities did not receive State aid for lunatics, and the insane were quickly transferred to the asylums. Workhouses should be utilised. Time was the test to be applied as to the condition of a patient. Hospitals would largely aid in gaining scientific acquaintance with brain disease. He favoured the building of asylums in blocks, by which means patients could be relegated to their proper quarters. The hurry and worry of the day tended to insanity in more incurable forms, and hence the percentages were not so favourable.

Mr. S. W. North (York) said he had advocated the treatment of incurable patients in workhouses, and was glad the idea was becoming fashionable. Great reform was needed in the early stages of the management of lunatics, as a large number of persons became insane for brief periods, and if they could have probationary treatment they would recover, many cases being due to want of food, intemperance, and a variety of circumstances.

Dr. Bevan Lewis (Wakefield Asylum) considered the provision for stemming disease in its incipient stages inadequate. A clinical staff would improve the tone of the asylum medical ordinary staff; whose assistants, too, should be supplemented. If they were to progress, they would require individualised observation and treatment. Boarding out in Yorkshire he regarded as impossible, owing to the density of the population and the great facility for communication. With an enlargement of the workhouse accommodation, more frequent medical attention, more skilled nursing, they might trust a large percentage of pauper lunatics to the care of the Guardians.

Dr. Douglas (Leamington) and Dr. Wiglesworth (Prescott) having spoken, Dr. Yellowlees (Gartnavel Royal Asylum, Glasgow) thought boarding out in agricultural counties might be encouraged. As to having separate institutions for the treatment of lunatics, Yorkshire had been particularly unfortunate in having distinguished men in care of the insane, so that the evils of joint institutions had not been fully recognised; and hence the West Riding had perpetuated at Wadsley, and now at Menston, what he believed to be a noble and magnificent mistake. We should have brain infirmaries, as well as eye and ear infirmaries, where patients could be first sent for consideration. One of these infirmaries in every large centre in Yorkshire would have been a much wiser and not more costly idea than the erection of the Menston Asylum.

Dr. Nicholls (Bloomingdale Asylum, New York) said that the State asylums in America corresponded with the county asylums in England. The States were being divided, however, into asylum districts, so as to make it accessible to the patients to be accommodated. The Willard Asylum had been provided altogether for the chronic insane; but this and others were too remote, and they were supplemented by cheaper buildings.

Dr. Merson (Hull) thought the plea that boarding out would not answer in Yorkshire was disproved by its success in Hull, where the population was dense. He feared that persons would not be very ready to take advantage of brain infirmaries. It was quite time the struggle as to the lowest maintenance rate should be put a stop to.

We have on several occasions reviewed the progress made in the treatment of consumption; and when sounding, as it were, so as to see in what latitude we were, we have found that so far as the indications held out, we have been sailing over the antiseptic sea. Consumption has been cured over and over again under almost every conceivable form of treatment, and since the anti-parasitic method has set in the cures wrought, by internal and external antiseptics, are no less wonderful than those wrought by the notorious Dr. Ramadge. M. Paul Cheron has recently, in the *Union Médicale*, given an analysis of the various new medicines used in the treatment of pulmonary phthisis. He has taken as the basis of his article the work published by Dr. Gilbert, of Geneva. Dr. Gilbert has classified the new anti-parasitic agents employed, in the following manner: (1) Medicinal inhalations; (2) pulverisations; (3) gaseous enemas; (4) injections; (5) internal antiseptic medication; (6) modification of the soil; (7) other external methods.

1. *Medicinal Inhalations.*—Carbonic acid has been tried since the work of Weill. Nothnagel and Rossbach believe it to be more hurtful than useful. Sulpho-hydric acid has been employed by Allevard, and studied by Niepce, on animals and human beings, who finds that the cure is frequent in the first and second degree, but in the third degree the disease progresses to a fatal issue. Sulphurous acid has been used by Dujardin-Beaumetz with great benefit, so far as regards the diminution of the expectoration

and the cough. Inhalations of benzoate of soda are useless. Prof. Sanchey Herrero (Valladolid) has proposed the balsamic inhalations, using Waldenburg's compressed air apparatus, interposing in the tube a flagon containing either essence of menthe or humid powder of iodoform. Dr. Ransome advises inhalation of ozonised oxygen 3 per cent., submitted to a pressure of from six to eight kilogrammes. He administers at the same time pilules of iodoform and cod-liver oil. The result has been that thirty phthisical patients have experienced diminution of night sweats and fever. There has been no change in the phthisical signs. Fluorhydric acid has been much more largely used. Scilla notes in ten cases improvement in the local and general states. In 1888, at the Congress on Tuberculosis held in Paris, Raimonde gave the results of this form of treatment on 128 patients. He noted twenty-eight cures, with disappearance of the bacillus. Eighteen patients with cavities have been much improved. Galger has obtained favourable results: in seventeen cases he observed five times complete disappearance of the bacilli in the sputa, with a considerable diminution of the phthisical signs; in seven cases he obtained a notable local improvement; twelve patients increased in weight, but the increase was not in constant relation with the local improvement. Two patients suffering from laryngeal phthisis suffered from inflammatory complications. Audollent draws the following conclusions from seven cases: Inhalations of fluorhydric acid appear to act more on the general health of the tuberculous than on the pulmonary lesion. The most marked effect is certainly the return of the appetite, while the dyspnœa, too, is modified. Gilliard has treated forty-six patients, and he believes that the inhalations are useful in the outset, and even in the state of softening, but the treatment should be conducted with care in emphysematous or rheumatic patients. He does not consider hæmoptysis or laryngitis contra-indications. Dr. Brunet has not recorded very encouraging results. He recognises the good effect on the appetite, but he attributes the improvement in sweats, dyspnœa, increase of weight, to the absolute rest enforced on the patient. Dr. Tisne has employed fluorhydric inhalations on forty-six patients, thirty-two of whom had not passed the second stage. Thirteen improved, sixteen remained stationary, and three became worse. Gilbert has employed the following solution: Fluorhydric acid, 300 grammes; water, 300 grammes. He has experimented on thirty patients—nineteen ameliorated, three aggravated, five died. The number of sittings has varied from 16 to 120. He notes the improvement of the appetite in all patients. Gilbert concludes that fluorhydric acid gives better results than other modern treatment. Dr. Cheron says on this that all the world is not of M. Gilbert's opinion, and that the only conclusion to be drawn is that the improvement which has resulted in some cases is no more remarkable than the improvement brought about by simple hygienic rules. We cannot despise the improvement of the appetite, especially in the phthisical, but the cures which were announced with so much *éclat* are not substantiated.

2. *Rectal Gaseous Injections.*—The Bergeron method is becoming less and less employed. It was taken up with great enthusiasm by some American physicians, and many kinds of apparatus were devised by ingenious instrument makers. It had no scientific foundation, and we need not waste any more time over its consideration.

3. *Pulverisations.*—MM. Nuguel and Rueff employed a solution of 1 in 1,000 of the biniodide of mercury under pressure. They have treated twenty-seven patients, nineteen ameliorated, eight stationary.

4. *Injections* (*Subcutaneous*).—Gilbert has employed eucalyptol, but without success; and Shingleton Smith has used phenate of camphor, but he has only experimented on two patients, with such results, however, that he thinks it worth while to repeat his attempts at local antisepsis. Intra-parenchymatous injections are now almost abandoned, even by their promoters.

5. *Internal Medication.*—A great number of new medicines have been employed. A few only are deserving of serious consideration. Dochmann and Martel praise calomel as one of the best of antiseptics; it produces diminution of the fever, sweat, and cough. Sticher has studied the administration of iodide of potassium. It is indicated when there is chronic interstitial pneumonia, fibrous phthisis, adhesive pleurisy, etc. There are certain contra-indications for its use, as hæmoptysis, lesions of the larynx, œdema of the glottis, interstitial nephritis, amyloid degeneration of the kidneys, purpura, pemphigus, and weakness of the heart. The iodide should not be given in a group in which the bronchal mucous membrane is affected. Laskoff has employed with success homeriana, a polygonaceous plant, which grows in Russia in the wild state, and which contains an irritant oil, which appears to be an irritant principle. He prescribes a decoction of infusion of the plant in affections of the respiratory passages, and especially in bronchitis and tuberculosis, curing 90 out of 112 cases of tuberculosis. The improvement is shown by lowering of the temperature and diminution of sputa. We need only mention two other substances—mutesia vicifolia and euchristine. Lashkeurck employed borate of ammoniacum in doses of thirty drachms three times a day, giving at the same time codeine and other sedatives.

Dr. Lamargne has just published an interesting work "On the Principal Modifications and Contra-indications and the Influence of Certain Mineral and Climatic Stations in the Treatment of Phthisis." According to Dr. Lamargne, we should not send a patient (1) in the acute or subacute stage; (2) who has hectic fever; (3) or who has pulmonary lesions generalized. In all these cases the fatigue, the change of habits, and the treatment, accelerate the fatal issue. The favourable conditions are, that the lesion be circumscribed, the form apyretic and chronic. Loss of appetite is an indication, for one of the first effect of hydro-mineral treatment is a re-awakening or increase of appetite. A good time to send the patient is when there is a remission of the symptoms. The principal French stations for tuberculosis are Allevard, of which we have already spoken,

Amelie-les-Bains, Cauterets, Les Eaux-Bonnes, Enghien, La Bourboule, Le Mont-Doré, Saint Honoré, Vernet-les-Bains. They are divided, according to their effect on tuberculous patients, into waters sedative and exciting, and are classed accordingly in decreasing order. Eaux-Bonnes, Cauterets, La Bourboule, Amelie-les-Baines, Saint Honoré, Allevard and Enghien, Mont-Doré and Cauterets represent the stations mixed, as all are more or less exciting according to their altitude. The tuberculous may be divided into torpid, with languishing nervosity, neuropathic, disposed to sanguineous congestion. The types may be mixed; the torpid must be sent to an exciting station, the excitable to a sedative station; Amelie-les-Bains solicits asthmatics and phthisicals; so the waters are divided into different classes. The patient should proceed to the station by easy stages selected, taking special hygienic precautions as regards clothing if it be in the mountains. The treatment should be conducted with the greatest care, so as to avoid complications; rest being enforced, and the most minute care being taken.

6. *Modifications of the Soil in which the Microbe Flourishes.* — Under this heading is included medicine, necrophytic, sur-alimentation, air. In the first place is to be placed arsenic, much vaunted by Buchner, and he has given it with the object of destroying the bacillus. Jacobi has also administered it to infants, in small doses. Feeding by means of a system known as Gavage has succeeded in certain hands, but it is not popular. Air plays an important part in the cure of phthisis, but this is really included under health resorts. We shall return to this subject again.

During the International Congress on Legal Medicine, lately held in Paris, the important subject of expert testimony in criminal cases came up for discussion. Many suggestions were made as to the best method of protecting the interests of the accused, and at the same time of vindicating justice. Amongst the chief speakers were some eminent legal professors, and it may not be without profit to give an abstract of the opinions expressed by some of the principal speakers.

MM. Guilliott and Demange drew up a number of conclusions, two of which were to the following effect: "The examining magistrate should be present at all *post-mortems* and examinations, in order to supply the expert with information and facts capable of throwing light on his researches." "The solicitor for the defence shall be present, in order to point out to the expert the objections for the defence." These two propositions formed the basis of discussion.

MM. Demange and Guilliot expressed themselves in favour of having an expert on the side of the prisoner, and this principle seems to be recognised in France and in Belgium; and the Congress so far ratified the principle that it passed the following resolution: "To protect the interests of society and the accused, there must be for all expert work not less than two experts. These experts, to be named by the examining magistrate, shall have the same rights, take the same oath, draw up one report, and receive the same rate of pay from the State." M. Moreau gave the weight of his authority to this proposal. Several speakers pointed out the difficulties there would be in carrying out this resolution; as, for instance, in certain provincial towns it would be difficult to find physicians of equal standing; and even in towns where a school of medicine is, the professor of medical jurisprudence would have an advantage over the expert who was not attached to a school. The official report would, of course, have to be submitted to a jury, and the expert be examined upon the report; and it is to be feared that with the jury the professor of medicine's evidence would have a greater weight than that of the other expert, but these are difficulties which could be overcome.

The Congress passed another very important resolution: "That the experts should be chosen out of official lists drawn up by public authorities, and by scientific bodies designated for that purpose." This appears to be an excellent proposition. When experts disagree, who shall arbitrate between them? This phase of the question was fully considered, and the following proposition adopted: "The system of the plurality of experts demands the establishment in the faculties of medicine of a superior council of legal medicine, whose duty it shall be to act as an ultimate court of appeal for disagreements between experts." The realisation of such a project appears to us to be very remote—certainly so far as England is concerned. Several other very important conclusions were suggested by MM. Demange and Guilliot, as, for instance, the following. "A course of study covering the general principles of legal medicine shall complete in the faculties of law the study of criminal procedure." "It is expedient, to facilitate the studies of legal medicine, to adopt, as an exception to the secrecy of the preparation of the case, that the *post-mortem* shall take place before the students following the lectures (as the habit has already been formed), the judge still keeping his right of veto." "It is advisable to form in institutions devoted to legal medicine, or in the record offices, archives and collections of objects that have served to convict criminals under the direction of magistrates and experts."

These conclusions are very important, and we believe are possible of realisation; and when we have students who have been trained on these lines, we shall have no difficulty in the selection of experts. The Maybrick case afforded an instance of disagreement between eminent experts, and it would be pleasant for the profession to have some system by means of which such differences might be settled without the publicity. Faith in the evidence of experts has been very much shaken by this trial. The conditions of France are rather different from those of England, and some of the resolutions passed at the Congress would have to be very much modified before they could be adopted in England, but the general principles which underlie these resolutions are applicable to all countries.

We have published from time to time several articles dealing with the subject of puerperal fever, and we have insisted upon the necessity of carrying out in connection with labour the strictest aseptic conditions. This may be achieved in many ways, though it is not necessary for success to use what we call antiseptics. We publish in another column an excellent practical paper, which confirms our views on this point. Puerperal fever is rare in careful, well-conducted midwifery practice; but we fear that it is far too common in midwifery as carried on by untrained midwives, and by the class included under the name of clever women. The poor require midwives. It is rather late in the day now to insist upon the necessity of trained midwives. The following case, taken from the columns of one of the daily papers, conveys a painful lesson, and shows us how far ignorance can go, and the destruction following on ignorance: At an inquest held on September 16th by Mr. Wynne Baxter, on the death of a woman from puerperal fever, the evidence showed that the mother and aunt of the deceased were in the habit of attending confinements, although they were unqualified. The aunt was reported to have delivered the deceased. It was, however, stated that the mother was present in the room at the time; and there was no evidence to prove that she did not make the examinations, although the aunt effected the delivery. It appeared from the evidence elicited at the inquest that the mother, Mrs. Lyddon, had had six other deaths in her practice since July 24th. She had received a warning from the coroner at an inquest held on August 5th, on one of her fatal cases, that she was not to attend any cases of midwifery for at least a fortnight. She did not pay any attention to this warning, and several of her patients died. The lay papers headed the account: "Deaths from Puerperal Fever—Extraordinary Evidence."

The contagious nature of puerperal fever has long been recognised by the profession; and before the days of antiseptics, we have had strict injunctions laid down on the precautions to be taken in the presence of this fatal disease. All the old writers insisted upon the necessity of the abandonment of midwifery practice for a time after the primary case. This rigid rule has been modified in modern times, for it has been proved that by strict precautions the danger of conveying the infection may be obviated. This woman erred in ignorance at first, but when warned by the coroner she persisted in the pursuit of her avocation, and here her conduct calls for animadversion. We believe we are correct in saying that she did not bring herself within reach of the law, even though death followed in her wake. The patients employed her at their own peril or risk. A charge of malpractice would follow against any medical man who acted as this woman acted. The law discriminates, but it leans, unfortunately, to the side of the unqualified. We trust that this terrible story may direct attention to the state of the law in England which allows anyone to practice midwifery, however imperfectly educated or ignorant. There is very little excuse at the present day for this state of things. Training in midwifery is brought within the reach of all who desire to take this pursuit up as a means of livelihood. Our lying-in hospitals open their doors on the most liberal terms. Some of our societies conduct examinations and give certificates to midwives. It is unjust to those who have gone through a course of training and examination to allow such women as the one recently brought before Mr. Baxter to pursue their calling. This is a question for the women of England to take up and to agitate upon. It is evident that the poor require protection, even against themselves. Trained nurses are an absolute necessity of our civilisation. The poorer classes evidently cannot discriminate. The remedy is simple.

Annotations.

"Forsan et hæc olim meminisse juvabit."

OUT-PATIENT REFORM.

The most grievous defect in our hospital system arises from the abuse of the out-patient department. We do not desire to be dogmatic, but we believe this point is conceded by all who have made a special study of the subject. We want the poor to reap the fullest benefits from our charity, but unfortunately it is not the poor who fill our out-patient rooms. People in good circumstances, and who are well able to pay, cadge on our charity, to the injury of the general practitioner, the latter being compelled, by the force of competition, to resort to all kinds of devices to make a living. There are difficulties where schools of medicine are concerned, and where teaching pabulum is required in divising a remedy for this abuse; but we believe that these difficulties are not insurmountable, that general practitioners have it in their power to settle the question. It remains to be seen whether they are willing to help.

A PHILANTHROPIC SCHEME.

We learn from the *Medical News*, U.S.A., that some young women college graduates, residing in New York City, propose to make a settlement in a bad tenement-house district, for the purposes of dispensing philanthropy and sanitation. Funds amounting to $3000 are in hand, and a large house of the olden time, near Ludlow-street, has been secured for occupancy next September. The young ladies will live there, in a locality of squalor and hopelessness, doing what they can to instruct and relieve the poverty-stricken mothers and children. They will be accompanied by a female physician. It is expected that the shortcomings of the municipal officers whose duty it is to enforce cleanliness of street and domicile will be noted and reported with great particularity, and in a way that sanitary results will necessarily follow. These colonists must all be graduates, and no one will be received for a shorter stay than two months.

MIDLAND VOLUNTEER MEDICAL ASSOCIATION.

AMBULANCE FIELD DAY.

The fourth annual field day for ambulance manœuvres took place at the Staffordshire Brigade Camp at Cannock Chase, on Monday, August 5th, by invitation of Colonel T. T. Fisher and officers of the 2nd Vol. Batt. South Staffordshire Regiment. The ambulance men of the 1st Vol. Bat. Royal Warwickshire Regiment with their waggon arrived by train at 11 o'clock at Hednesford Station. The South Staffordshire battalions sent their ambulance detachments to meet the visitors, together with the bugle band of the 1st North Staffordshire, headed by which they marched up to the camp. Surg. Major Clark, of the 2nd South Stafford, was in command, there being also present Surg. Partridge, acting as adjutant in the place of Surg. Wilson, who had unfortunately met with a severe accident, and Surg. E. L. Freer (1st Vol. Bat. Royal Warwickshire Regiment), the hon. secretary of the Association. Detachments from the 1st Notts Rifles (Robin Hood), in their neat green uniform, and from the 1st Derbyshire Regiment arrived later, as did the ambulance detachment from the 2nd Vol. Bat. North Staffordshire Regiment, which came by the road from the Hagley camp. Rations were served out to the detachments at one o'clock. and they and the 2nd South Staffordshire Regiment paraded shortly before three o'clock for the business of the day. The following are the particulars of the detachments :—1st Vol. Bat. South Staffordshire Regiment, two officers (Surg. Major Smith and Surg. M. Jackson), two non-commissioned officers, sixteen men ; 2nd Vol. Bat. South Staffordshire Regiment, two officers (Surg. Major Clark, in command, and Surg. Partridge, acting adjutant), two non-commissioned officers, sixteen men, one bugler, and a waggon ; 3rd Vol. Bat. South Staffordshire Regiment, two officers (Surg. MacMunn and Acting Surg. Magrane), two non-commissioned officers, eight men, one bugler, and a waggon; 2nd Vol. Bat. North Staffordshire Regiment, two officers (Surg. Majors Morgan and Lowe), one non-commissioned officer, twelve men, one bugler, and a waggon; 1st Vol. Bat. Derbyshire Regiment, two officers, (Surgeon Gentles and Vaudrey), two non-commissioned officers, twelve men, one bugler; 1st Vol. Bat. Notts Regiment, Staff-Sergt. Worth, and eight men, Surgeon Major Manby (3rd Vol. Bat. South Staffordshire Regiment), acting as brigade surgeon, was also present, as were Surgeons Charlesworth and Phillips, of the 1st North Staffordshire, which regiment did not provide a detachment, but it should be stated that one is in course of formation and will be available next time. The ambulance detachments formed two companies and were drawn up in the rear of the 2nd South Staffordshire Regiment, the whole of them marching past in column, with the waggons two abreast covering the flanks following in the rear. The movements of the troops were much impeded by the presence of a large concourse of spectators, who wandered about indiscriminately between the companies. The manœuvres took place in the vicinity of the camp on the lower ground below the reservoir. After a considerable amount of wheeling and marching over some very rough ground, the attack was gone through, men falling out as wounded according to the usual plan, with tallies attached representing supposed injuries, and volleys being fired. Two waggons, those of the Warwickshire Regiment, and the 3rd South, were stationed at the left rear, where the collecting station was under Sergeant-Major Morton ; Surgeons Freer and Gentles being in command of the bearer companies, and further away two tents were quickly pitched as a dressing station. Surg. Major Morgan was here in charge, and behind these were the other two waggons. The wounded men were brought to the rear in waggons of second line, the lifting of the stretchers and the moving of the wounded being carried out strictly in accordance with the prescribed methods, but as the crowd more or less filled the spaces between the "battlefield" and the ambulance stations, the manner in which all the work was done could not be seen. The improvised splints and the bandaging on the field appeared to be smartly and cleverly done, and the detachments seem to be well acquainted with the work allotted them at the different posts, impeded as they were by the crowd's demonstrative sympathy for the wounded. The officers were entertained by Colonel Fisher and officers of 2nd Vol. Bat. South Staffordshire Regiment.

HOSPITAL ADMINISTRATION.

The Commission on Hospitals, we regret to say, will only examine into the state of the metropolitan hospitals; we did hope that the provincial hospitals would have been included in the investigation. But though the provincial hospitals do not come within the scope of the enquiry, it will still be possible for the Committee to take the evidence of some provincials, who are acquainted with the grievances and defects not only of the metropolitan, but of the provincial system of hospitalism. The abuse of charity is as great in Liverpool, Birmingham, and Manchester, as it is in London. It is only a matter of degree. London of course has the questionable advantage of possessing a larger number of hospitals than any other city ; we see no justification in this fact for the narrow scope of the enquiry.

VOTING BY PROXY.

Many arguments have been brought forward in favour of voting by proxy at the election of the Council of the Royal College of Surgeons, England. These arguments have had such cogency, and were so reasonable, that this reform has been introduced. The time has now come to consider the advisability of extending the same privilege to all members of the British Medical Association, so that those who are unable to attend should be able to exercise the privilege of voting on resolutions submitted at general meetings of the Association. There is much to be said *pro* and *con*, and we gladly offer our columns for the ventilation of the subject.

GROWTH OF AMBULANCE WORK.

It is evident that there is still great scope for ambulance work in London. There are an immense amount of deaths in that city from accidents—something like eight a day. Putting the number as low as six fatal results a day, and the total number of accidents at thirty per day, we still have numbers large enough to indicate a great deal of pain and suffering. A return from a factory district in the north-west of England, representing an operative population of six millions, gives an almost identical census of deaths and accidents as that of London. However, employers of labour and their workpeople seem to be fully realising the value of the instruction offered by the St. John Ambulance Association, and freely co-operate in forming branch associations. There is now in England no religious denomination that has not organised classes for education in this matter, and the work has extended to the remote countries of the far east. Already half a million persons have been instructed, and 170,000 certificates and 12,415 medallions have been granted for proficiency. It is to be hoped that these numbers will swell rapidly, and that there may be a great increase in the ranks of those who are not compelled by their own ignorance to stand inactive in the presence of suffering, and are unable to assist in alleviating those constantly-occurring accidents which a huge growth of population and machinery render an inevitable and daily event.

A NEW USE FOR THE PHOTOGRAPH.

The New York City Board of Health has declared war against the overcrowding of tenement-houses, and as a first step it is proposed to have positive proof as to the extent of the over-population. This is to be obtained by the taking of photographs at midnight by means of the flash-light. Some of the inspectors are photographers, and have already tried the process as a means of demonstrating and perpetuating curious unsanitary conditions in their respective districts. And now the Board has decided to adopt this graphic method as a form of official record. It will assist in making up the history of "Hell's Kitchen," the "House of Blazes," and "The Bend," and will serve to illustrate future annual reports. The Board will enforce another requirement of the tenement-house law, which is frequently ignored by the landlords, and which directs that water shall be placed on every floor of houses of that class.

PROSECUTION OF UNQUALIFIED PRACTITIONERS.

The Medical Defence Union, during the brief period of its existence, has made its power felt for the protection of the profession. Its recent action against the Birmingham quacks should commend it to the support of the profession. The substantial results obtained in the shape of fines levied on the Birmingham charlatans will hardly recoup the Council for the expenditure they have incurred in these prosecutions, so that general support must be given if the warfare is to be continued. The society is now admirably organised. Branches have been established in all the counties with thoroughly representative committees, and for the first time we have a cheap and feasible scheme of self protection. The fee for membership is small. Union makes force, and by a large membership, each contributing a mite, we can crush the hydra-headed monster.

CONCUSSION OF THE SPINE.

Dr. H. H. Smith (*Journal American Medical Association*) concludes a paper thus:

1. Concussion of the spinal cord is no longer a matter of doubt, but may some times occur as the result of various forms of violence (there being nothing peculiar in the application of the force to the body), as the result of derailment or collision of railroad trains.

2. The pathological changes noted in the molecular structure of the cord as the result of shaking, jarring, or so-called concussion of the cord, when attended by paralytic symptoms, may be due to a hæmorrhagic effusion, or be shown *post-mortem*, in softening, and localised, or limited atrophy. In cases due to hæmorrhage, the symptoms may be improved by judicious treatment, and permanent disability prevented.

3. The possibility of pre-existing neurasthenia, or hysteria, or fraud, on the part of a claimant, should be carefully noted in forming a diagnosis in these cases.

4. As the question of permanent disability justifying exemplary damages is frequently raised in claims of the kind alluded to, it should be recollected, in forming a prognosis, that numerous cases are reported of recovery or marked improvement in a few weeks, and one in three years even, after the occurrence of paralysis.

5. No physician should go into court and swear that a plaintiff has had a concussion of the spinal cord, or of its nerves, unless he has proved the disturbance of the normal functions of the cord, as shown in sensation or motion, or both, and that the symptoms appeared *soon* after the injury.

THE PHILOSOPHER'S STONE.

FATAL EXPERIMENTS.

American mail news state that at Cincinnati the doctors have decided that the man Steele, into whose system the Brown-Sequard elixir was injected, has blood-poisoning. He will sue for $5,000 damages. Felden Weir, whose wonderful cure was telegraphed broadcast, is in bed again. Great hard lumps appear where the incision were made, and he is delirious. Dr. Longfellow, who made the first experiments, says he has lost all faith in the elixir. Dr. Langinbeck, the chemist who prepares nine-tenths of all the elixir used in Cincinnati, says it is dangerous if used after an hour, and rank poison if used after two hours. It is reported that the workhouse physicians have experimented indiscriminately, with frightful results. Several fatal experiments are also reported in other places.

THE GERMAN CODE OF ETHICS.

This code should be universal. 1. Every kind of public laudation, whether it proceeds from the physcian himself or from others, and continued advertising in the public papers, is to be reprobated.

2. The designation of "specialist" for puffing purposes is to be reprobated.

3. The public offering of medical assistance gratis, underbidding in concluding contracts in sick societies and the like, offering advantages of any kind to a third person, in practice are inadmissible. The designation "Klinik" and "Poliklinik" (hospital) belong exclusively to institutions which serve the purposes of instruction in connection with universities.

4. The ordering and recommending of secret remedies are inadmissible.

5. Any attempt of any kind, on the part of a physician, to intrude upon the practice of another is dishonorable, especially in the case of one who has acted as a substitute for another, or in consultation. A practitioner must by no means undertake the treatment of the case without the express assent of the previous physician. A specialist called in for a definite part of the treatment must confine himself strictly to that.

6. No physician is at liberty to make disparaging remarks to others about another physician.

The faithful observance of these rules would greatly advance the interests of both profession and people.

IRRESPONSIBLE IMBECILES—WHAT SHALL BE DONE WITH THEM?

The American *Lancet* has a very good article on this subject, from which we give an extract. There is a considerable class of persons to whom belongs fairly the appellation of irresponsible imbeciles. They are capable persons, often very efficient tradesmen, mechanics, business men, until they partake of liquor. Then they lose all control, and become destructive to the well-being of the community. These persons are sent to either insane asylums, jails, or prisons; yet they are neither insane nor criminals in the proper sense of those terms. Society should provide such care for these men that they may not destroy themselves by their excesses, or burden society by their improvidence. We have known many such, in whom it seemed clear that they could be cured if they could have held over them an indeterminable sentence by which, on the first approach of an indulgence in alcohol, they could be placed in a house of refuge, and compelled to work at their employment till such time as it seemed wise to order their release. Some of these cases are reached by religious influences, and reformed. Others are reformed by the agency of inebriate asylums, but the majority are not to be reached in this way. Neither religion, mental reasoning, nor medicine avails ought with them. Under the present arrangement of society they cannot be cared for in any place with any success or satisfaction. One such person we have observed for many years. When not under drink, he was a very capable, useful man, but under drink, he was ugly, abusive to his friends, a thief, etc. His friends exhausted every means of saving him from himself. Finally, they placed him in an inebriate asylum for a long period, till he was pronounced cured. Relapsing from this he was sent to another asylum, and still another. At last, for some theft committed, he was sent to prison. This was repeated several times, he again relapsing as soon as he was discharged. Finally, in despair, he was classed as insane, and sent to an asylum. But he has no place in an asylum for the insane. He should be in a house of detention erected for such as he. On being committed to this, they should be given an opportunity to labour for their own support, while under guardianship. This house of detention would be a genuine work house. Inebriates sent to these work houses under an indeterminate sentence, should be kept till it was apparent that their will-power and mental integrity had been restored. Thus they would be treated upon their own merits, and treated as enemies to themselves and to society.

DR. OLIVER WENDELL HOLMES.

A despatch to the daily press says that Boston's typical son, Oliver Wendell Holmes, celebrated his 80th birthday on August 29th, and despite its informal character the anniversary was a most charming one. He spent the days at his summer home at Beverly Farms. This is a quiet place, liberally embowered in vines and flowers, and most suited to such a festival. The flowers outside the house were nearly equalled by those within, the gifts of friends, which had been sent in the early morning. From nine o'clock throughout the day until nightfall there was a continuous succession of visitors, mainly from the neighbouring north shore estates. The doctor, seated in his comfortable library, with his attractions and alluring furnishings, received all his friends with a bright and pleasant smile and hearty cordiality. His surroundings added much to the charm of the occasion, the room being a genuine old-fashioned study of the kind our grandfathers loved, with a tall, quaint firescreen and open fireplace, with its blazing logs resting on the ancient firedogs, whose polished brass standards reflected the careful housewife. The floor was covered with neat matting and a mammoth rug spread out before the fire. In one corner was a simple rolltop desk, and in another a book-case with the doctor's favourite authors convenient for ready access. The chief charm of the entire interior was its thorough homelikeness. One of the many pleasant features of the day was the coming of the children. In the forenoon the boys and girls of Beverly Farms school, to the number of twenty-six, called in a body, and were given a most cordial reception, the doctor entering heartily into the feelings of his little friends, giving each a warm shake of the hand and his friendly smile. To each he presented a pretty bonbonnière filled with sweets, tied with a bright bit of ribbon, and bearing on its cover a miniature vignette of the poet, with his name beneath. The children of the neighbour-

hood came in the afternoon, and the lovely, shaded roads and bypaths were filled with white clad little maidens going and coming. Besides flowers there were many other pretty souvenirs of the anniversary. Among them was a handsome cup, presented by lady friends of the doctor. It bore the following motto :—

Aug. xxix., mdccclxxxix.

"'Tis the heart's current lends the cup its glow,
Whate'er the fountain whence the draught may flow."
—*The Pledge of Friendship.*—O. W. Holmes.

THE NEXT MEETING PLACE OF THE BRITISH MEDICAL ASSOCIATION.

The place of meeting for 1890 has not yet been fixed on. We should gladly see it held at Torquay. The following extract from the *Torquay Times*, September 14th, indicates the feeling of that town : "A golden opportunity of disseminating a knowledge of the climatic and other advantages of Torquay throughout the length and breadth of the land, upon the continent, and in America, now presents itself; but unless prompt action be taken the chance will be lost, never posssibly to occur again. The British Medical Association, we are informed, are prepared to hold their next year's congress in Torquay if an invitation be given to them. We shall now see if there is sufficient public spirit existing amongst the inhabitants of Torquay to prompt them to avail themselves of such an opportunity of securing the best and most enduring advertisement that could possibly be devised. The annual meeting of the British Medical Association is usually attended by from 1,200 to 1,500 of the leading men of this country, representing a constituency of 15,000 registered practitioners, and by delegates from France, Germany, Italy, and other European countries, as well as from America. It is impossible to overrate the importance to Torquay of the meeting within its borders of such an assemblage of the most learned men of the medical profession, all of whom would return to their respective *clientele* impressed with the validity of the claims which Torquay puts forward to be regarded as one of the healthiest of health resorts in England. The subject was mentioned at a meeting of the sub-committee of the Torquay Town Association on Wednesday evening, and there was an unanimous concurrence of opinion that if the executive of the British Medical Association could be prevailed upon to come to Torquay it would be of incalculable benefit to the town. Unlike agricultural societies, who expect a guarantee fund to be raised in the town they purpose visiting, the Medical Association make no such stipulation, but simply look for a good old-fashioned English welcome. That this would be extended to them if they resolved to accept Torquay's invitation there is not a shadow of doubt, and the hospitality of our leading residents, our beautiful situation on one of the most magnificent bays on the English coast, and the grandeur of the scenery around us, would, no doubt, serve to render the meeting of 1890 memorable in the annals of the Association. The principal requirement would be the provision of rooms adequate to the accommodation of so large a body, and fortunately the town possesses in the Bath Saloons a suite of assembly rooms admirably adapted for the purpose, and which the Local Board, we should imagine, would be only too glad to grant the free use of.

"A DOCTOR FOR TWOPENCE."

The above was the title of an article in one of the London evening papers. It gave the following account of the Finsbury Dispensary :—"The benefits conferred by a well-managed dispensary in a poor and crowded district are often incalculable. Ever since the year 1870 the poor and unfortunate who have attended the valuable institution situated in Brewer-street, Goswell-road, known as the Finsbury Dispensary, have had good reason to be grateful to the founders and all connected with it. When a *News and Post* man visited it on Saturday there was an exceedingly large number of patients who were eagerly waiting there turn to see the doctor. They had gathered together from all parts of the compass—from the parishes of St. Giles Without, Cripplegate, St. Sepulchre Without, St. Andrew's, Holborn, Islington and St. Luke's, Clerkenwell and Pentonville, and the City. What scenes of suffering, privation, self-denial, and anxiety did the anxious crowd represent! All that is required to obtain medical advice and medicine at the Finsbury Dispensary is a recommendation from a governor of the institution, which also provides medical relief at their own homes for such patients as live within the district, but who may be incapable of attending at Brewer-street. There are two physicians, who take charge of those unable to attend the dispensary, besides a surgeon for the surgical cases, and a resident medical officer. The institution is open for two hours daily (Sundays and public holidays excepted), remaining open for such further time as the attendance upon the patients applying within the hours named may require.

"The dispensary is said to be the second oldest in London, and it is certainly one of the most important of its kind. It was founded by George Friend, a benevolent Quaker, 109 years of age, at St. John's Coffee House, St. John's-square, Clerkenwell. It is principally owing to the perseverance with which this excellent charity was conducted by the founders, and the solicitude shown to the sufferers who sought its assistance, that the dispensary has been able to command such a wide field of public sympathy and support. There can be little doubt that Finsbury Dispensary has been established on a solid and enduring basis. Since its foundation over 900,000 men, women, and children, in all parts of the metropolis, have been relieved by its agency. During last year 17,751 new letters were given to patients, there were 37,185 attendances at the institution, whilst 3197 visits were also paid to patients at their own homes. In fact, no application for relief was refused in the hour of need.

"All who knew anything of Finsbury Dispensary knew also Mr. Richard Moreland, senior, who has been the honorary secretary for the past thirty-seven years. Although

now in his eighty-fourth year, he is still busily engaged in its management. His grandfather took a great interest in the charity when it was first founded. Mr. Richard Moreland started, in 1833, the firm of Richard Moreland and Son, engineers, in Old Street, and continued an active member of it until 1883, when he handed over the business to his son, Richard Moreland, junior. He married in 1830, and his two daughters as well as his son took a great interest in the work at the dispensary. When one of them died a short time ago she left a substantial legacy of £100 in aid of the funds. Mr. Moreland has filled the office of chairman both of St. Luke's and St. Mary's, Stoke Newington. He is connected with a number of charitable agencies, holds strong views on hospital reform, and his brain is ever active in devising schemes for the benefit of the dispensary, as well as of his poorer neighbours. Mr. Moreland is a venerable looking gentleman with long white beard and striking features, which stamp him as one who is never weary in well-doing. May he be long spared to continue his good work, and may the operations of the Finsbury Dispensary be every attended with success."

A NEW LITHIA WATER.

There has lately been introduced an entirely new natural mineral water, entitled the St. Marco, and as there are few waters of this class we direct attention to it. It is a sparkling, effervescing water, with a faint saline taste, and, owing to its effervescence, it will be found extremely palatable and useful as a dinner water. It may be taken in the natural state, or may be mixed with wine or whisky in doses of one to three tumblersful per diem. Its use in Italy by some eminent Italian physicians in the hospitals and private practice is attended by the introducers of the water, and favourable reports on its efficacy in gout and rheumatism have been received by us. The water is bottled by means of the syphon system, and in this way the natural gas is retained. The following analysis has been made by Professor Amoroso, representing the saline and mineral constituents present in 1000 grammes of the water of St. Marco.

Sulphate of Calcium	Gr. 1,270465
Sulphate of Magnesium	0,104558
Chloride of Sodium	0,281774
Chloride of Magnesium	0,107797
Carbonate of Calcium	0,274000
Carbonate of Magnesium	0,005131
Carbonate of Potassium	0,017843
Carbonate of Sodium	0,047175
Carbonate of Lithium	0,036768
Carbonate of Iron	0,003625
Carbonate of Manganese	0,004402
Neutral Phosphate of Calcium	0,003658
Silicic Acid	0,018000
Alumina	0,026500
Boric Acid	Sensible traces.
Nitric Acid	Sensible traces.
Total	Gr. 2,201696

We intend testing the efficacy of the water, and then make a further report upon it.

THE OPENING OF THE SCHOOLS.

The great work of medical education commences to-day —viz., the opening of the medical schools. We have published in our advertising columns the prospectuses of some of the best schools; and we may briefly allude to their respective advantages. No inaugural address was given at the London Hospital, but a dinner of the old students, under the presidency of Dr. Langdon Down, took its place. The advantages of the London Hospital are well known. Its locality and close proximity to the docks insure but a too plentiful supply of surgical cases. The fees are very reasonable, and lodgings can be obtained in healthy neighbourhoods also at reasonable charges. Students are taken by a number of medical men living close to the hospital, and dinner and refreshments are provided within the precincts of the college. Full particulars may be obtained from the warden.—At St. Mary's the session will be opened by Dr. Maguire. This hospital, owing to the energy of the Professors, has taken a first place in the list of educational institutes. It is admirably situated, and its fees are also reasonable. Residential chambers and registered lodgings can be easily secured in the neighbourhood of the college.—At St. George's the introductory address will be given by Dr. T. Clifford Allbutt.—St. Bartholomew's will open without an introductory address.—Dr. P. S. Abraham, so well known for his researches on leprosy, will open the Westminster Medical School, and Mr. Godlee will perform a similar service at University College.—We have so recently alluded to the Leeds School of Medicine as a place of study that we need not repeat our enconiums upon it. In our next issue we shall be able to publish some of the introductory addresses.

Periscope.

I.—GLEANINGS IN MEDICINE.

By W. B. Kesteven, M.D.

On the Use of Eucalyptus in Headache. By Morris J. Lewis, M.D. (*The Medical News*, Philadelphia, July, 1889).—The administration of doses of oil of eucalyptus three or four times a day has been found beneficial in headaches of various types when other means have failed. Eight cases are related by Dr. Lewis, who states that the remedy had been employed with satisfactory results by Dr. Weir-Mitchell and Dr. Linkler, at the Infirmary. The drug appears to be most useful in headaches of the congestive type, especially when given at the onset of the attack. Further trials are contemplated by Dr. Lewis.

Cholelithiasis with Obstruction of Cystic Duct; Successful Cholelithotomy. By Edward Willis Way, M.B. (Edin.), Lecturer on Obstetrics and Gynæcology in the University of Adelaide (*Australasian Medical Gazette*, June, 1889).—Mrs. B——, æt. twenty-two, consulted me early in 1888, for a tumour in the right hypochondriac region. The history did not suggest any previous attack of biliary colic or the occurrence of an obstruction in either the common or the cystic duct, and as the tumour appeared to be cystic in character, I thought that it would most likely prove to be a hydatid of the liver. My patient was admitted into the North Adelaide Private Hospital, where, on February 8th, with Dr. Lendon's assistance (Dr. Aitken also being present), I performed an exploratory abdominal section. On reaching the tumour, an aspirator needle was inserted, and some clear fluid drawn off, confirming, as I thought, my diagnosis. The cyst was then secured with silk ligatures, drawn out of the wound, and incised, whereupon a considerable quantity of fluid escaped, together with a large number of

small gall stones. The finger was then introduced into the gall-bladder, and many more small calculi removed, together with one solitary large concretion. It was next discovered that the cystic duct was occluded by a stone of considerable size, which was firmly impacted. This was, with much difficulty, broken up into fragments and scooped out of the duct, which was inverted as far as possible into the gall-bladder for that purpose, and when this had been done the bile found its way out freely. The wound of the gall-bladder was then stitched to the abdominal parietes with silk in the usual manner. The subsequent progress of the case was satisfactory, and there was no constitutional disturbance. Bile-stained fluid was, however, discharged very copiously for some time, and the sinus did not close until some weeks had elapsed. The patient is now in perfect health.

On the Use of Borate of Ammonia in Pulmonary Disease (*L'Union Medicale*, August 8th, 1889).—This medicine is very highly recommended by Dr. Lashkewich for administration in phthisis, especially in the early stages of the disease; he has known it rapidly reduce expectoration and fever. The dose has been thirty centigrammes (1 centigramme = between $\frac{1}{8}$th and $\frac{1}{7}$th gr. English). Codeine or other sedatives may advantageously be combined with the borate of ammonia.

Comparative Results in Pleurisy with reference to the Development of Phthisis Pulmonalis. By Vincent Y. Bowditch, M.D. (*The Medical News*, Philadelphia, July, 1889).—The results of the investigations by Dr. Bowditch are thus stated:—"1. That whether we can prove absolutely, by such statistics, that all pleurisies are tubercular or not, yet a large percentage of those patients who were afflicted with pleurisy, often in apparently chronic forms, recover their health, and have never had any recurrence of the original trouble, nor development of subsequent pulmonary or otherwise tubercular trouble." "2. That while undoubtedly there are many cases in which an attack of pleurisy is followed within a comparatively short space of time by pulmonary trouble, and, therefore, special care should be taken during convalescence, yet we are not justified in giving such gloomy prognoses as we should be inclined by accepting the extreme views held by Landouz and his followers."

Case of Recurrent Laryngeal Tumour. By W. F. Quaife, M.B. (*Australasian Medical Gazette*, June, 1889).—M. H——, a healthy man, of middle age, had been troubled for twelve months with a growth in his throat, which impeded more or less his speech, respiration, and ability to swallow. At times it broke away, but always recurred, at each the symptoms became urgent. A large trilobate fibrous tumour was situated above the true cords, and nearly filling up the glottis. This was removed by means of a laryngeal ecraseur. A week afterwards another tumour was found, pressing upwards from beneath the cords, attached to the right cord near the angle of the glottis. Though it did not interfere with the breathing, it prevented the cords coming together. It was removed by the cord snare, but with a little more difficulty than the other on account of the protection afforded to it by the cords. The seat of growth was destroyed by crystals of chromic acid, delicately applied on a silver probe, which was found more efficacious than the electric cautery. There was some paresis, which interfered with vocalisation, but which gradually passed away under the use of strong silver solution, and after a little faradisation the voice became perfectly useful; it recovered the whole of its natural timbre, though not to the full of its natural strength. A large quantity of cocaine was used, partly in spray, partly with brushes and cotton holders.

Cryptopinum (*Der Fortschritt*, July 20th, 1889).—This substance is an alkaloid, sometimes met with in opium, and belonging to the codeine series of alkaloids. As with codeine, narcotine, thebaine, and papaverin, poisonous narcotic symptoms are induced by it; it exerts also a controlling influence over tetanic symptoms. Cryptopinum (C_{21} H_{23} NO_5) is a strong base, neutralising mineral acids, and is readily soluble in boiling alcohol, from which it crystallizes out in small nodules.

Rhus Aromaticus in Incontinence of Urine (*Der Fortschritt*, July, 1889).—The juice, or a tincture of the leaves of this plant, have been administered with good effect by M. Eloy, in doses of from twenty to twenty-five drops.

Carissa Xilopieron—American Bitter Cup (*Der Fortschritt*, 20th July, 1889).—The tree from which this article is made is of the American order—*Apocyneæ*. Its leaves are opposite, the flowers are umbel. Cups are turned from the wood, which, when filled with water or wine, after a time, impart thereto a bitter flavour. This liquid is administered as a febrifuge, stomachic, and vermifuge. In the Mauritius, where the plant is known by the name of "bitter-wood," it is used as a tonic, diuretic, and febrifuge. It is also prepared as an alcoholic mixture, as well as an aqueous infusion, and is administered in intermittent fever as supplementary to quinine.

II.—SELECTIONS FROM CONTINENTAL MEDICAL JOURNALS.

By G. F. Cadogan-Masterman, M.D.

Les Tics et les Ticeurs. By Dr. Charcot.—From the great excitability of our southern neighbours, the instable equilibrium, as it were, of their emotional centres, we should expect to find amongst them not only examples of the most extravagant forms of madness, but extreme oddity in speech and gesture associated with apparent sanity. And it would seem, too, that French alienists have an especial zest in discovering and recording those sad cases in which the pitiable and the grotesque are commingled so strangely, and arranging and sub-dividing the species, much as botanists do the genus *Rubus*, to the confusion and dismay of all less enthusiastic observers.

In an inaugural lecture in the course on "Nervous Diseases," Prof. Charcot enumerates a number of these, and calls them examples of tic—a word which we use only in the compound tic-doloreux, and necessarily associate with pain—that is, clonic convulsion; a form of intermittent palsy affecting usually single groups of muscles, and due to periodic changes in the brain, minute explosions of incöordinated energy at more or less regular intervals.

He showed one patient who, about three or four times a minute, brushed his right hand across his face as if to remove some troublesome insect, sometimes striking his face involuntarily with considerable force; and due, apparently, to a source of irritation at the centres of the fifth and sixth cervical nerves.

This form is seen under many modifications—jerking movements of the head, of the eyes, of the hands and the feet—and they may be so slight as to be a mere trick or habit, or pass into graver developments. Probably the worst are those in which the sudden movement is accompanied by an involuntary cry which may take the form of articulate words, for the reason that these words are often of an indecent kind. This is called coprolalia (*κόπριος, filthy*), which we sometimes find associated with aphasia. The sufferers are frequently ladies, well bred, and highly educated, and their distress in being irresistibly compelled to utter words and phrases of which they acutely realise the shocking impropriety, and yet which they cannot suppress, is most painful to witness. The impulse itself strongly resembles epilepsy in the suddenness and domination of the attack; and if they do not give way to it, but utter the dreaded words under their breath, there is a feeling of acute restlessness, of pent-up passion, which may relieve itself in acts of maniacal fury. Prof. Charcot gives many cases, with revolting verbal details he seems to revel in enumerating, but which we may well pass by. One singularity is that all these cases are examples of heredity, the only exception was that of a girl whose mother was housekeeper to a "ticeur" of pronounced type during her pregnancy.

Another form is that of the "doubter," who examines a letter a dozen times before posting it—cannot make up his mind to post it unless he tears it out of the envelope to read every word he already knows by heart, and then firmly believes he has forgotten the stamp. One man cannot see a razor without a passionate impulse to cut someone's throat with it. Another cannot travel by railway without a restless desire to wrench the door open and throw himself on to the line. Then there is the *misophobe*, who cannot touch certain objects, such as a piece of copper, without the idea of irremovable defilement, who washes his hands a dozen times and still cannot rid himself of it—yet perfectly sane in all other respects.

There are others who suffer from *agarophobia*, of which he gives no example, and *claustrsphobia* (*κλανστικὸς, complaining*). An extraordinary theory of one of his patients was that inanimate bodies were always fretting when they were still! that chairs and tables, bottles and vases, were perfectly miserable unless they could shift their position, and, as they could not do it themselves, she was incessantly moving them about the room, and yet they were not happy, for their nights were as still as her own were restless!

Some years ago I treated a case resembling Charcot's tic, happily of only short duration; a middle-aged primipera had been attended in my absence by a *locum tenens*, and had had severe *post-partum* hæmorrhage. On my return I found her suffering from puerperal mania, her mental balance had been upset by the resulting anæmia; she had refused all food, and sat up in bed incessantly waving her right arm and shouting "From the devil and the doctor, good Lord deliver us. Amen!" And this had been going on for twenty-four hours. With some difficulty I got her under the influence of chloroform, and, then, just as consciousness was returning, induced her to swallow the contents of a tumbler containing two raw eggs, a tablespoonful of brandy, and—this was before the invention of the Pravaz syringe—a full dose of morphia. She was asleep in a few minutes, and when she awoke some hours later, was perfectly sane. She told me afterwards, with much shame and contrition, that she was fully aware of the extremely uncomplimen-

tary nature of the allusion to myself, but could not help shouting the words to relieve a feeling of suffocation which oppressed her.

One of the Parisian cases was that of a man who had an irresistible desire to know and record the name of every man he met; he took infinite pains to secure the purposeless information, and could never trust the list out of his sight.

Such are a few of the endless vagaries of the insane—of tic and the sufferers thereof.

III.—NOTES FROM FRENCH JOURNALS.

By H. R. Hatherly, M.R.C.S.

Hot Water Injections in Epithelioma of the Neck of the Womb (*Gazette de Gynécologie*).—The effects of hot water injections in cancer of the uterus forms the subject of a paper by Dr. Tornery: no radical cure can be expected, but some of the most distressing symptoms are relieved. The vagina may be thoroughly disinfected by syringing twice daily, with water at a temperature of 39° or 40° C., for about half an hour. The ichorous discharge is much lessened thereby; hæmorrhages are much diminished, and the general condition of the patient is improved. In the majority of cases pain is so far diminished that hypodermic injections of morphia may be dispensed with. In some instances, epitheliomatous masses contract, harden; their bulk is diminished, and the invasion of the disease appears to be arrested. Unfortunately, it is difficult to follow up such cases for any lengthened period, for as soon as relief is afforded they leave the hospital. In one case the improvement continued for four months. It is true that a fatal result is only retarded, but it is a great point gained if suffering can be relieved to any considerable extent.

Horny Excrescences, and their Transformation into Malignant Neoplasms at the Base (*Journal de Médicine de Paris*).—According to Dr. Paul Gilles, it happens occasionally, although rarely, that horny growths are developed on various parts of the human body. These excrescences occur in both sexes, and at all ages, but especially in the aged. The horns may grow from either skin or mucous membrane, but chiefly affect the head. They may be single or multiple, simple or compound; sometimes several will arise from the same base. Their size varies from that of a pin head to that of a ram's horn; they gradually contract as they grow from the base to the summit. They are usually pointed at the extremity, although sometimes bulbed. The pain caused is very trifling, and only occurs when there is laceration or inflammation at the base. These growths are seldom curable; if removed, they are either reproduced, or the base becomes a malignant neoplasm. The operative treatment consists in a double incision circumscribing the base of the horn, the forcible wrenching out of the horn, and energetic cauterisation of the wound.

Therapeutic Uses of Salicylate of Mercury (*Journal de Médicine de Paris*).—Dr. Malècot prescribes this remedy simultaneously with santal oil for blenorrhagia, and has been struck with the absence of all pain even when the injections have been repeated at short intervals. It seems to be an urethral antiseptic, possessing all the efficacy of the salts of mercury hitherto employed, without causing pain; far more powerful than boric acid, it is quite as innocuous. Dr. Silva Aranjo claims—(1) That salicylate of mercury is easily tolerated by the stomach; it causes no gastralgia, enteralgia, colic, or diarrhœa, which so commonly result from other mercurial preparations. (2) Salicylate of mercury does not produce salivation. (3) Administered internally, salicylate of mercury is more rapid in its action than any other salt hitherto used. Dr. Riche, in a communication to the Academy of Medicine, states that there are four sorts of salicylate of mercury. One sort contains 42 per cent. of metal, and another contains 59 per cent., and these two kinds should not be prescribed indifferently, their action being dissimilar.

Treatment of Hydarthrosis of the Knee (*Annales d'Orthopedie*).—Dr. Georges Berne has adopted a plan of treatment of synovial effusion, in those cases which resist the usual methods of treatment, which has proved very successful. The treatment consists of a forcible rupturing of the synovial sac, which he terms *éclatement*, and which is followed by massage. The knee is semiflexed, when it may be noticed that the fluctuation is more marked above and inside the knee; the fluid is circumscribed, and the tumour formed is rendered tense by pressure with the hand; firm pressure with the thumb, or percussion with the edge of the closed hand, will produce an indentation, followed by a diminution of fluid effused. There can be no doubt but that a rupture or fissure of the synovial sac takes place at its weakest point—perhaps at the level of its insertion; the fluid permeates in the neighbourhood of the lymphatics and veins, which are so abundant in the cellular tissue surrounding the joint. The rupture is easily effected in ecent cases, as the membrane has not become thickened, and possibly the effusion is more liquid. After the *éclatement*, massage must be persevered with, directed from the knee towards the groin, the form of massage being strong and deep centripetal pressures. The method is as free from danger as it is simple in execution.

Society of Medical Missions (*L'Union Médicale*).—A society has been formed in Paris, the object of which is to establish dispensaries and hospital schools in Africa and in the east, in order to counterbalance the power of the English and German Medical Missionary Societies, which have been instituted to resist the influence of French medicine, formerly predominant.

Pharmacology of the Iodides of Potassium and Sodium (*Gazette Hebdomadaire de Montpellier*).—Dr. Gay, who has been studying this question, has formed the following conclusions: (1) The iodides of potassium and sodium of commerce are generally impure: the druggist should be very careful to examine these drugs, and to reject all containing less than 95 per cent. of iodide, or which contain iodate. (2) The iodide of sodium has always a weaker percentage, from 80 to 85 per cent.; the dried iodide is not purer than the crystallised; medical men should allow for these facts in their prescriptions. This salt, which is very hygrometric and difficult of manufacture, would perhaps be better abandoned. (3) The iodide of potassium may be obtained pure at a reasonable price, and its preparation is one which pharmaceutists might undertake for themselves. The preference given to iodide of sodium by some physicians is not justifiable.

IV.—NOTES FROM RUSSIAN, POLISH, AND SWISS JOURNALS.

By Valerius Idelson, M.D., Berne.

Bacteriology of Puerperal Fever.—In the *Vratch*, No. 30, 1889, p. 659, Dr. Matvëi M. Mïronoff, of Kharkov, publishes a preliminary note on his bacterioscopic researches (in Professor V. P. Kryloff's laboratory), undertaken for studying the etiology of puerperal fever of milder forms. The principal results of the author's investigations may be summarised as follows:

1. In cases of puerperal endometritis, the uterine and vaginal discharges contain a streptococcus which is present in pure, or almost pure, cultivation.

2. In cases of puerperal pelvic inflammations associated with exudation, the discharges contain either the streptococcus with a staphylococcus, or the staphylococcus alone.

3. In such cases where the womb or vagina contain some decomposing dead tissues (retained placenta, vesicular mola, etc.), the extremely fœtid uterine and vaginal dscharges prove to teem with peculiar rod-shaped microbes, which occur either alone or are accompanied by scanty non-pathogenic bacteria of various species.

4. The puerperal streptococcus is quite identical with Fehleisen's streptococcus of erysipelas. [There is no difference whatever in their morphological properties and biological behaviour. Besides, the inoculation of the former coccus to rabbits and man gives rise to a distinct erysipelatoid attack.]

5. The puerperal bacilli are fairly thick and short (almost ovoid). They are, as a rule, arranged in pairs, which form irregular small-sized heaps. They grow well both on jelly and agar, but somewhat less so (especially in the absence of air) in broth. On gelatine they form large circular colonies of a yellowish-orange colour, without liquefying the medium. When cultivated in test-tubes, the microbes develop in from four to six days a characteristic offensive putrescent odour, closely resembling that of the puerperal discharges from which they have been obtained. When inoculated to animals they do not produce any local changes, but give rise to fever, the febrile elevation oscillating between a few tenths and 2° C., and lasting from four to eight days, according to the quantity injected. [The results of the experiments most closely tally with the clinical facts observed in the cases indicated *Sub* 3: in all the patients examined by Dr. Mïronoff, only mild fever—not higher than 39.5° C.—but no local changes were present.]

6. Hence, mild puerperal affections may be subdivided into two large groups, one of which embraces *specific* cases caused by the penetration into the patient's genital tracts of certain pathogenic microbes (streptococcus or staphylococcus). The other group consists of *non-specific* affections determined by the absorption into the patient's circulation of certain ptomaines that are elaborated by the putrefaction bacilli described above, in the presence of putrescent substances (dead particles of animal tissues).

On Umbilical and Uterine Murmurs.—Having carried out two series of careful observations in Professor Breisky's clinic, Dr. L. Ettinger, of Zurich (*Zurich Inaugural Dissertation*, 1888), arrived at the following conclusions:

1. *Umbilical Murmurs.*—(*a*) In an overwhelming majority of cases

the umbilical murmurs heard through the maternal abdominal wall arise in the umbilical cord itself. (*b*) They are caused by some compression of the umbilical vessels, produced either by twisting of the funis round some parts of the fœtus, or, less frequently, by the formation of genuine umbilical knots, or by the cord being too short. (*c*) In exceptional cases, however, the *bruits* originate in the fœtus's heart. (*d*) At all events, the term, "umbilical murmurs," is quite correct, and should not be replaced by any other denominations.

2. *Uterine Murmurs* (100 cases).—(*a*) They are present in a vast majority of cases of normal labour (in 88 out of 100). (*b*) Most frequently (in 63 out of 88) they are heard on the left side of the abdomen, but sometimes (in 12) on the right, or on both sides (in 10), and now and then (in 3) all over the patient's abdomen. (*c*) The cause of the murmurs most frequently occurring on the left side should be sought in the physiological displacement and rotation of the womb towards the right side. The supposition is supported by the fact that in cases of right-sided murmurs the uterus proves to deviate from the said physiological situation. (*d*) As a rule (in 60 out of 88 cases), the uterine *bruits* heard during labour can be still detected for a certain period after the parturition. (*e*) In multiparæ they invariably persist by far longer than in primiparæ.

Medical Poisoning by Male Fern.—In the excellent Polish monthly, *Nowiny Lekarskie*, May, 1889, p. 225, Dr. Alkiewicz (pron. Alkevitch), of Pobiedzisk, details a very instructive instance of severe toxic effects produced by the internal administration of ethereal extract of male fern in a rather liberal dose (on account of tape-worms). The patient, an otherwise quite healthy lady, æt. thirty, who, on a former similar occasion, had been given ten grammes of the remedy without any bad consequences, took this time, at 8 a.m., twenty grammes of the extract, dissolved in tincture of cinnamon. During the day she had several fairly profuse stools, while about 6 p.m. she suddenly fell into a deep and prolonged swoon. When seen by the author shortly after her coming round, she was in grave collapse, with hardly perceptible pulse, accompanied by incessant nausea, retchings, vomiting, tremor of hands, and general restlessness. In about two hours, under the influence of an assiduous administration of champagne, ice, and black coffee infusion, the alarming symptoms began to gradually subside, and the utterly exhausted lady fell asleep. On the next day she was still weak, while on the third there developed an intense jaundice, which lasted for several days, to disappear spontaneously. Pointing to his case, Dr. Alkiewicz strongly warns against using large doses of the extract recently recommended by Dr. J. O. De Man, of Middelburg (*Therapeutische Monatshefte*, January, 1889), who advises to give from 17.5 to 32 grammes to women, and from 10 to 15 to children. The maximal dose for a woman, however strong and healthy she might appear, should not surpass 15 grammes, and for a man 17.5. The circumstance that Dr. De Man did never happen to meet with any toxic effects from administering 25-gramme doses may be explained simply by his mode of using the remedy. He prescribes it invariably in capsules, some of which probably pass through his patient's digestive tracts quite intact.

[We should say that even such large (and proportionately expensive) doses, as suggested by Dr. Alkiewicz, are altogether superfluous. In the *Allgemeine Medic. Central-Zeitung*, No. 103, 1883, Professor Aufrecht, of Magdeburg, recommends an excellent plan for expelling tape-worms by means of male fern. Given a patient above eighteen years of age, order him to swallow a good purgative dose of castor-oil about the night-fall, and let him abstain subsequently from any food, except, perhaps, a small-sized piece of meat, with some white bread. On the next morning, give him twelve gelatine capsules (best of all, operculated), containing each about six decigrammes of ethereal extract of male fern (therefore, not more than *seven* grammes of the extract, in all), to take them with his coffee. About half an hour after the breakfast, the patient should eat a slice of white bread, and the "cure" is complete. In one or two hours, certainly not later than in three, the patient will demonstrate to you triumphantly his abominable tænia with head and all (which head may be occasionally sold for five francs to collectors and makers of biological preparations—so that a happy "host," or a proprietor of a tape-worm farm embracing five or six parasites, might make a fairly profitable bit of "business"). As far as the reporter's experience is concerned, he never yet failed to expel the worms after Professor Aufrecht's simple, rapid, and relatively cheap plan, and that even in such cases which had been previously for years vainly treated by all possible "patented" and unpatented remedies.—*Reporter.*]

Epistaxis from Atropia.—In the Kïëv ophthalmological bi-monthly, *Vestnik Oftalmologïï*, May and June, 1889, p. 264, Dr. Mikhaïl I. Reich, of Tiflis, publishes a remarkable case of quite unusual toxic effects of atropia. A rather delicate, but generally healthy pupil of a local college, æt. seventeen, with a good (non-hæmophylic) family history, applied on account of progressive myopia. The ophthalmoscope revealed slight staphyloma posticum and posterior choroiditis. The treatment (absolute physiological rest of the eyes, etc.) included the instillation of an atropia solution (1 to 120), two drops into each eye twice a day. On each occasion the instillation of the drops was followed in about five or ten minutes by a profuse nasal bleeding of fifteen minutes' duration. On examination on the third day, the patient was found rather pale, his pupils dilated, but such symptoms as dryness of the throat or giddiness were absent. The instillation being discontinued for two days, the bleeding at once ceased to appear; but as soon as the administration was resumed the patient again began to bleed, and that still more profusely than previously. The same phenomenon, though in a somewhat lesser degree, was also produced by a correspondingly strong solution of sulphate of duboisin.

V.—OBSTETRICS AND DISEASES OF WOMEN.

THE MEDALS OF BENJAMIN RUSH, OBSTETRICIAN.[1]

By Horatio R. Storer, M.D.,

of Newport, R. I.

Recently, during researches relative to a paper upon the medals, jetons and tokens illustrative of the science of medicine, at present appearing in the *American Journal of Numismatics*, I learned of a gold medal conferred by the Society of Medicine of Caen, France, upon the late Dr. Jean Charles Faget, of New Orleans, a graduate of the University of Paris, Chevalier of the Legion of Honour, and distinguished as an author in various departments of medicine.[2] With the impressions of this medal that have been kindly sent me by Dr. Faget's family, I have received copies of a portion of his works. Among them is an interesting brochure, published at Paris by the Baillières, entitled, "L'Art d'apaiser les Douleurs de L'Enfantement" (The Means of Assuaging the Agony of Parturition).

THE CLAIM OF RUSH TO THE TITLE OF OBSTETRICIAN.

In this memoir, Dr. Faget quotes a striking statement by the most eminent, perhaps, of American physicians, Dr. Benjamin Rush, for many years professor of the institutes and practice of medicine and of clinical practice in the University of Pennsylvania. In discussing the symptoms of labour, and as if directly anticipating and answering in advance the objections that were to be urged half a century later in his own city, by the celebrated Dr. Charles D. Meigs, Dr. Rush had said: "By some divines these symptoms, and particularly pain, have been considered as a standing and unchangeable punishment of the original disobedience of woman, and, by some physicians, as indispensably necessary to enable the uterus to relieve itself of its burden. By contemplating the numerous instances in which it has pleased God to bless the labours and ingenuity of man, in lessening or destroying the effects of the curse inflicted upon the earth, and by attending to the histories of the total exemption from pain in child-bearing that are recorded of the women in the Brazils, Calabria, and some parts of Africa, and of the small degrees of it which are felt by the Turkish women, who reduce their systems by frequent draughts of sweet oil during pregnancy, I was induced to believe pain does not accompany child-bearing by an immutable decree of Heaven." And again: "I was encouraged (in this) by having known delivery to take place, in one instance, during a paroxysm of epilepsy, and in another during a fit of drunkenness; in both of which there was neither consciousness nor recollection of pain."[3]

The notable passage referred to above, as reproduced by Dr. Faget in his French monograph, is the following: "I have expressed a hope in another place that a medicine would be discovered that should suspend sensibility altogether, and leave irritability, or the power of motion, unimpaired, and thereby destroy labour pains altogether."[4]

The "another place" to which Rush here makes allusion is a letter dated May 12th, 1802, to Dr. Edward Miller, entitled "On the means of lessening the pains and dangers of child-bearing, and of preventing its consequent diseases." In this, when speaking of cases "where the absence of throes and the slow progress of delivery indicate a deficiency of muscular irritability in the fibres of the uterus," Dr. Rush shows the advantage of opium, and goes on to say, "I think I have seen the

[1] Read at the Fortieth Annual Meeting of the American Medical Association, held at Newport, R. I., June, 1889.

[2] The biography of this gentleman will be found in our Permanent Secretary, William B. Atkinson's work, "The Physicians and Surgeons of the United States," Philadelphia, 1878, p. 44.

[3] "Medical Inquiries and Observations," third edition, 1789—1811, iv., pp. 373, 374, 376.

[4] Ibid., p. 376.

happiest effects from that excellent medicine in such cases, in destroying useless pains and shortening the progress of labour. How far a medicine (if such can be found) so powerful as wholly to suspend the sensibilities of the nerves, without impairing their irritability, might succeed in destroying pain altogether, I know not."[5]

In this letter, aside from the special point that I make in the present paper, Dr. Rush demonstrates, throughout, that he was a skilful obstetrician. In its very title, he closely associates the pains of labour with its dangers; he announces that they can both be lessened; he recognises that they are the potent cause of subsequent disease; and he teaches its prevention. Here, as in the passage quoted by Dr. Faget, Dr. Rush foreshadows the great discovery which has taken from parturition its anguish, without interfering with its progressive natural action, and has greatly lessened its perils to mother and child.

Upon referring to the work of Walter Channing, of Boston—a native, by the way, of Newport, and upon this occasion to be spoken of with especial honour—to whom, as also to Sir James Y. Simpson, as the first physician to induce artificial anæsthesia in childbirth, Dr. Faget gives due credit, I find this comment: "It is grateful to recur to the opinions of our distinguished countryman (Dr. Rush) on a point which he approached with sentiments of the profoundest reverence, on account of the authority on which it is supposed to rest; whilst he successfully controverted the popular inference—namely, the penal character, involving a physical necessity of pain in labour." He had conceived a "hope. Was it not prophecy? Had it not so much truth as a basis, that the great discovery of our own day seems to be the revelation of that truth? His doctrines were rather inductions, or the generalisations of facts, than theories." He "expresses a 'hope' of the discovery of a remedy of (obstetric) pain," but he also states "the reasonableness, the moral evidence, of that hope, so that it becomes faith."[6]

It will be noticed that Rush distinctly contemplated the removal of sensibility alone, and the retention of uterine activity. His views, therefore, were precisely those of the best authorities of the present day, regarding the conduct of natural labour. He was in general sympathy with Sydenham, whose works he edited, and for whom he even named his country seat, and it is not unlikely that through studying upon this account the more closely the effects in labour of opium, his opinion of which I have already quoted—and that preparation of it which is known as Sydenham's to the present day—he came to perceive the end that was to be searched for in childbirth beyond merely soothing its pain—namely, the preservation unimpaired of uterine contractility and expulsive power. Dr. Rush, besides, was far in advance of his time in recognising the evil effects of alcohol upon the human system, both in health and disease. One of the cases which he reports was of painless labour "during a fit of drunkenness." This would have added to his desire to produce the effect, temporary anodynia, while avoiding its disreputable and injurious cause.[7]

That Rush had anticipated by nearly fifty years the magnificent idea which was to result in freeing woman from the burden of incalculable suffering that had been borne by her through the ages, seems to have been recognised by no one besides Channing, save Faget and one single other.

In 1876 Dr. Gaillard Thomas both noticed and quoted Rush's aspiration, yet he seems to have mentioned it as but an incident in the course of his generous tribute to Simpson, the more striking from appearing in the very same book wherein was made the direct implication, of course an accidental one, that the anæsthetic property of chloroform was an English and not a Scotch discovery.[8] Dr. Thomas, in speaking of the introduction of anæsthesia into the lying-in chamber as an era in the history of obstetrics, thus declares: "It is somewhat singular that after the discovery of anæsthesia in this country, after the prediction, long before its discovery, by one of America's greatest physicians, that 'a medicine would be discovered that should suspend sensibility altogether, and leave irritability, or the power of motion, unimpaired, and thereby destroy labour pains altogether'; after it had been employed here in hundreds of cases for surgical operations, this link of the chain should have been forged by a European. Yet such was the case, and far be it from any American to begrudge him one atom of the glory which he deserves, or to endeavour to dim its lustre by 'faint praise.'"[9]

We do not find Rush's prophecy where of all places it would have most naturally been looked for, in the bitter letters of the elder Bigelow of Boston, in 1869 and 1870, to Sir James Simpson, nor in the minute statement, six years later, by his son,[10] although both of these gentlemen were colleagues of Channing in the Medical School of Harvard University.

Channing seems to have been the first to discover the great suggestion made by Rush. His reference to it in 1848 was apparently perceived by none till Thomas in 1876—thence by none till Faget in 1880, who again was unaware of the allusion to it that Thomas had made. From 1880 till now there exists the same utter silence as before.

I make this statement with hesitation, for the fact seems incredible. Several friends, however, have assisted me during the present investigation. From the treasurer of the Rush Monument Association, and ex-president of our own, Dr. J. M. Toner, the person of all now living probably most familiar with the life of this signer of the Declaration of Independence, I have received for examination many biographies of Rush,[11] from his own very extensive collection of medical works now in the Congressional Library, and he has besides aided me in the search itself. Dr. Toner writes me as follows: "I have nowhere found allusion to the wonderful hope expressed by Dr. Rush." Dr. Paul F. Mundé, of New York, who as editor for so many years of the *American Journal of Obstetrics*, aside from his own special researches in this direction, has had reason to keep informed of all that has been published upon midwifery, reports a similar result. "I do not recollect," he says, "ever seeing the name of Dr. Rush in this connection. Certainly he had a remarkable gift of prophecy!" Dr. James R. Chadwick, of Boston, the founder of the great medical library at Boston, and a most faithful observer of all that occurs in obstetrics, writes me to the same effect. "The prophecy of Dr. Rush was new to me. I have not seen it alluded to by any writer. It is of very great interest." And Dr. Gaillard Thomas, whom alone besides Channing and Faget I had found alluding to Rush in this connection, informs me that he recollects no one who has appreciated Rush's prophecy save Channing.[12]

You and I would, I think, have felt aggrieved had it been intimated that we were unfamiliar with the works of Rush and of Channing, and the chapter by Thomas, but for myself I am willing to acknowledge that having eyes I saw not, neither did I understand. With all my interest in the general subject, the full significance of Rush's true position towards this question, has not struck me until now." A student at Harvard University during the first use of sulphuric ether at the Massachusetts General Hospital, and though still an undergraduate a witness of many of the earlier operations during which ether was there employed—a friend of Dr. Charles T. Jackson, whose gold medal from the Swedish Government commemorates that, however he would have neglected of himself to communicate the discovery to the world, the idea of employing sulphuric ether as an anæsthetic was due to him, a pupil of Channing, and of Simpson, whose great Montyon gold medal from the Institute of France was not given merely for his other transcendent merits, but because by annulling the pains of childbirth, he thereby removed the primal curse, and

Among other memoirs of Rush, besides the usual Cyclopædic ones that I have consulted, have been that contained in Thacker's American Medical Biography (Boston, 1828), and the admirable "Benjamin Rush and American Psychiatry," by Dr. C. K. Mills, of Philadelphia (*Medico-Legal Journal*, December, 1886).

[12] I had not recognised Rush's place, or Faget's either, among obstetricians, when I prepared my paper upon the medals, jetons, and tokens illustrative of obstetrics and gynæcology (*New England Medical Monthly*, November and December, 1886).

lessened in almost equal degree both infantile and fœtal mortality, and by employing chloroform as the agent was better able than with ether to momentarily suspend sensibility, in Rush's language without impairing uterine irritability—and having myself twenty-six years ago, in 1863, contributed by an essay upon the subject[13] that Thomas in the "Century of American Medicine," already referred to, was kind enough to call "of considerable value," [14] to the work these preëminent philanthropists had commenced in reference to the general employment, even in natural labour, of artificially induced anæsthesia, I have yet failed, till the present moment, to properly recognize Rush in one of the most beneficent of the many labours of which he was engaged. His work as a sanitarian had been duly appreciated.[15] He had published papers upon diet,[16] climate,[17] military hygiene,[18] leprosy,[19] hydrophobia,[20] and yellow fever,[21] and for his great services during the epidemic of the latter in 1793, he had received unusual honours; among them gold medals from the King of Prussia in 1805, and the Queen of Etruria in 1807, and a diamond ring from the Czar of Russia in 1811. The chief point upon which, I predict, his lasting fame will rest was, however, wholly unappreciated during his life, and now, seventy-five years after his decease, it seems to have escaped the notice of all his biographers, and to have been but three times alluded to by writers upon midwifery.

Very interesting, moreover, appears the fact, to which Dr. Faget has also drawn attention, that Dr. Rush studied at the University of Edinburgh, and had access to that wealth of mediæval medical literature in its library in which Simpson so revelled, and whence he was accustomed during his researches into obstetric medicine, surgery and sanitation, to adduce so many wholly forgotten precedents. As a student myself of that ancient school, I can appreciate the influences that formed Rush's character, as observer, medical philosopher and practitioner. Born near Philadelphia in 1745, Dr. Rush took his degree at Edinburgh after two years of study there in 1763, and he proved Scotch in his subsequent methods of thought and of action, till his death in 1813.

Channing again was a pupil of Rush, to whom it was always his delight to affectionately refer. He graduated as a physician at the University of Pennsylvania in 1809. Through Rush's influence it was, undoubtedly, that he in turn resorted to the University of Edinburgh, and there drank from the fountain that had inspired his preceptor. It was not till 1812 that he received his medical degree at Harvard. He retained through his life his affection for the Scotch capital. His relations with Simpson were intimate, and it was his delight that while Simpson was the originator of actually induced anæsthesia in midwifery, he himself was the first American to urge its general use for this end. So far as the realization and final employment of obstetrical anæsthesia are concerned, Edinburgh, through Channing its American, as well as Simpson its direct representative, well earned its palm. It is strange that the first conception of the idea should also have been by a foster child of Edinburgh, Dr. Rush. Again, Drs. Channing and Charles T. Jackson were friends and close neighbours. They had long before occupied the relations of teacher and pupil. They lived upon the same street, their houses being but a few yards apart. They were upon confidential terms of acquaintance, with similar tastes for abstruse research in very unusual directions. The only wonder now is that the one, knowing the need of suffering woman which Rush at the very commencement of his medical studies had taught him, for an artificial solace at the time of her greatest physical trouble, and the other, having discovered and bearing for so long in his mind the anæsthetic qualities of the agent which gave the first step towards the solution of the problem—that these men should not have come more closely together, and the obstetric world's great secret been earlier made known. Jackson was an accomplished chemist, and searcher for recondite applications of his science to art, and Channing a most remarkable medical antiquarian. With Channing as his coadjutor, Jackson would not probably have been so grasping for riches and for fame as he proved when associated with Morton, though this may have been but the dremonition of the mental malady which, as in the sad case of his competitor, Horace Wells, occasioned his death—while poor Morton, jealous and all tenacious to the last, died, though more suddenly than Jackson, just as consequentially. The fearful quarrel, that involved in its scandal wellnigh the whole profession of the time, and indeed almost the good name of science itself, would perhaps thus have been avoided, and the birth of the divine idea might not have been, as it was, attended by the sundering of intimate personal ties, by deep distress and by wailing, the echoes of which have as yet scarcely ceased.

There is a strong parallel that may be drawn between the posthumous estimates of the two illustrious physicians of whom I have chiefly spoken in the present communication. It was at the close of the meeting of the American Medical Association at Washington, in May, 1870, that the news was received of Simpson's death, telegraphed by his son to your present reader within a very few moments after the event had occurred, and there are undoubtedly those now here who recollect with what regret the announcement was received by the Association, and the solemnity of the memorial meeting which was held immediately afterwards by its delegates and the medical residents of Washington. Whatever the previous feeling of individual members of the profession, in favour of ether or of chloroform as an anæsthetic, or regarding the respective claims of Boston and Edinburgh, which had improperly been made to seem antagonistic, all cavil was silenced at the touch of death. It has been so also with Dr. Rush. The rivalries of his time, which were intense, are forgotten. His own city, to which in his lifetime he was no prophet, points to him with pride. The great professional centres of our continent vie with each other in recognising him as the most fitting representative of early American medicine, and the chief ornament of the far reaching University whose distinguished provost is one of the orators at the present meeting of the Association. Seventy-six years have now passed since the death of Rush. It is but of late, as our lamented ex-President Gross said of our equally great McDowell, that "the chaplet that should have been worn on his brow has been placed by a grateful profession upon his tomb." [22] To add a fresh leaf thereto is not my privilege merely, but a filial duty. It is seldom that a man can trace back for a hundred years the influences that have shaped his own life and the little work he may have attempted to accomplish for medicine. Rush was at Edinburgh in 1768. It was entirely through his advice that thither went his pupil Channing. It was by Channing's influence that it became my own Mecca in 1854. Sincerely grateful, therefore, I am to Rush, and delighted to aid towards the high esteem in which he will henceforth be held by our obstetrical brotherhood. Should the question ever arise, from the sequences that I have endeavoured to trace, whether Simpson, like Channing, had appreciated Rush's prophecy, I am sure from what I know of his character, that such could not have been the case. He ever freely gave of his knowledge to the world, concealing nothing, and he was particularly generous in his treatment of Americans, whether living or dead. Even after Channing had quoted Rush, the full meaning of the American prophecy seems to have escaped Simpson, as it has us all, else he would have been sure to have used it, sharply, when replying to the senior Bigelow, equally unaware of its existence. The latter of Simpson's answers to the Boston sage was written, it will be remembered, from his deathbed. It was his farewell to the profession, of obstetrics and at large—happy, he said, "if it tend to fix my name and memory in their love and esteem." [23] At such a solemn hour, had he clearly

understood what we now know of Rush, his would have been the hand, promptest of all, to give justice where it was due.

Just as John Bell, of Edinburgh, in 1794, urged the performance of ovariotomy, and in 1809 it was successfully accomplished by his pupil, Ephraim McDowell, of Kentucky, so in 1802 or thereabouts Dr. Rush, a graduate of Edinburgh, foresaw the possibility and need of obstetrical anodynia, and it 1847 his dream, by all forgotten, became reality at the hands of the Edinburgh professor, Dr. Simpson.

Dr. J. R. Chadwick has asked me if Rush could have been familiar with Joseph Priestley's laboratory experiments with nitrous oxide. I have no doubt that such was the case, aside from the fact that after 1794 Priestley was a neighbour of his in Pennsylvania, and most probably also a personal friend. (It is another curious coincidence that a near relative of the philosopher, Dr. William O. Priestly, of London, should have been one of Simpson's best loved, and subsequently most disguished pupils.) It is moreover possible that Rush had noticed what Davy had just then suggested, in 1800, regarding the use of nitrous oxide as a purely *surgical* anæsthetic. However this may be, the fact remains that Rush had advanced far beyond the point assumed by Davy. What he desired and foretold was not the destruction of sensibility alone, but the retention with this, in full activity, of a certain usually dormant, but in obstetrics all important, system of nerves. Davy made no reference to allaying the pains of childbirth. His whole thought was of *surgical* anodynia, the mere quieting of general sensibility. He evidently never dreamed of obstetrical anodynia, where nervous irritability and uterine contractility must be retained unimpaired. And so with Boston. To Boston, indisputably, belongs the honour of having first demonstrated the general practicability and safety of induced surgical anæsthesia, against which there did not exist the then seemingly grave theological objections that were so vehemently urged against its *obstetrical* employment, and which made the triumph in this direction the more difficult, and yet for this very reason the more to be commemorated.

THE RUSH MEDALS.

I have thus briefly presented Dr. Rush's claim to be honoured by you, gentlemen, the teachers, cultivators, and practitioners of midwifery in the United States. Eventually, the memorial determined upon by this Association, in collecting the funds for which Medical Director Gihon, U. S. N., Dr. Geo. H. Rohé of Baltimore, ex-President Toner of Washington, and others of our Committee, have laboured so faithfully, will be erected, and mankind will be reminded of "the Sydenham of America."[24] It remains for you to influence the profession toward the hastening of that time, marking at last "the Rush renaissance."[25] Meanwhile, that you may contemplate the features of the man himself, and appreciate the better the parallel that has been drawn between him and the great light of British medicine, I show you reproductions, from my own collection, of the two medals that have been struck in his honour at the U. S. Mint, of which he was long the Treasurer. They have been photographed for me from the originals, greatly enlarged, by my friend, Mr. Clarence Stanhope, of Newport, and I wish that copies could be placed in every medical, historical and public library in the country. The following are their descriptions:

1. Obverse. Bust, with queue, to left; a neck cloth under the collar. Beneath shoulder, F (urst). Inscription: BENJAMIN RUSH, M.D., OF PHILADELPHIA.

Reverse. A river, flowing from side to side forwards; in background, the setting sun, with clouds and mountains. Large trees in foreground, to right; to the left, SYDENHAM. In front, a block of stone, on which: READ—THINK—OBSERVE. Upon this, an open book. Beneath, to right: M (oritz). FURST FEC. Exergue: A (nno). MDCCCVIII.

Silver (?), bronze, lead. 41 mm. 27.

The legend upon the reverse is from the close of his lecture, "On the Causes which have Retarded the Progress of Medicine." It is very similar to the "HEAR, READ, MARK, LEARN," upon an old medal of Christ's Hospital School, London, which is in my collection, in silver.

I have this medal of Dr. Rush both in bronze and lead. It is also at the Surgeon-General's Office at Washington, from the Lee Collection, in the former of these metals. It is very rare, and seems unknown to all numismatic writers. The die cutter, Fürst, was at the time an assistant engraver at the U. S. Mint.

2. Obverse as in preceding.

Reverse. An altar, upon which rests an open book. In front, upon an oval panel, a bust of Æsculapius, with serpent-encircled staff. In another panel, at right, an urn. Beneath, to right: M. Furst Fec. Exergue: A(anno). MDCCCVIII.

Bronze, gilt bronze. 41 mm. 27.

Unknown to all writers upon medals. Still rarer than the preceding. It is in the Lee Collection and my own.

I have endeavoured, but thus far in vain, to ascertain, the history of these medals, and have been aided in my enquiries by Dr. Wm. Pepper, of Philadelphia, through whom I have received letters from Hon. A. Loudon Snowden, long Superintendent of the U.S. Mint, and Mr. R. A. McClure, in charge of the Mint Cabinet. Col. Snowden has written, under date of March 21, 1889: "The Dr. Rush medal is not in the Mint Cabinet, and its history is obscure," and again upon the 27th, "I have taken considerable trouble to seek information from several sources, but thus far without any particular success." Mr. McClure, like Col. Snowden, was aware of the existence of but the first of the medals described above, and this he had seen at Mr. Alexander Biddle's. He reports: "Mr. Biddle did not succeed in finding any information or clue to the occasion of the striking of the Rush medal. I went to the Ridgway and Philadelphia Libraries, and the rooms of the Historical and Philosophical Societies, and looked over the file of two daily papers of 1808, the year in which the medal was struck, and found nothing." Messrs. Bailey, Banks and Biddle, prominent medallic artists of Philadelphia, have also been unable to furnish me with the slightest information. From this will be perceived the extreme rarity of the medals, and the fact that though both of them were struck at the Mint, the very existence of one of the two had passed from the knowledge of the Mint authorities. Of the first of them, there are said to be known two specimens in silver. It was remarked several years ago,[26] before the revival of an interest in medical numismatics, that these would be cheap at $20 each. They would probably now bring very much more than this sum, and it is to be hoped that they have been secured for permanent preservation by medical institutions, though as to this I am as yet uncertain.

The portrait bust of Dr. Rush upon the medals was undoubtedly from sittings for the purpose, since they were executed five years before his death. It will therefore be of service, in connection with the familiar painting by Sully, in giving his exact features for the monument undertaken by the Association, when at last its construction shall be commenced.

In conclusion, a brief quotation from the "Elegiac Poem on the Death of Dr. Rush," may not seem out of place:

> "Unchecked by ridicule, unawed by rules,
> Fallacious dogmas, and the pride of schools;
> With all the ardour of inspiring youth,
> From fair experiment, the test of truth,
> Deep-searching Rush ingenious reasonings drew,
> Bold to defend, and potent to subdue!
> Determined truth by every means to try,
> Where others dared not gaze, 'twas his to fly;
> He rescued truth from mad opinion's maze,
> And caught from Science her inspiring rays;
> Beamed o'er the healing art a radiant light,
> Like orient phosphor o'er the mists of night."[27]

How appropriate beyond the intention of its writer, who was but lamenting his decease, is the following, to Rush's supreme anticipation of the discovery and application of artificially induced anæsthesia to midwifery!

> "Thy light, bright Science, to this sphere confined,
> Was far too little for his mighty mind!
> Which soared above this world, and broke away
> From darkened nature to a world of day."[28]

A Plea for the General Adoption of Anæsthetics in Labour. By Mark B. Smith, M.D., McPherson, Kansas (*Medical Age*).—This is a subject of untold interest to both the physician and the parturient patient. From the time of the first employment of ether by Sir James Y. Simpson down to the present, they are many who oppose any and all means that will relieve the pangs of childbirth, basing their opposition on Scriptural grounds ("In pain and travail shalt thou bring forth"), apparently forgetting that the first parturition recorded in Holy Writ, and the only one in which man was the chief participant, points directly to such relief: "God caused a deep sleep to fall upon Adam!"

Among other arguments we find the following: "The effect would lessen or abolish maternal instinct:" "It is immoral, as producing a

[24] The above term was first applied to Rushby his friend and biographer, Dr. Lettsom, of London. Loc. cit., London, 1815, pp. 3-15.
[25] C. K. Mills. "Benjamin Rush and American Psychiatry." *Medico-Legal Journal*, December, 1886—Reprint, p. 2.

[27] Loc. cit., Philadelphia, 1813, p. 15. [28] *Ibid*, p. 31.

kind of intoxication;" "Dangerous, because of peculiar idiosyncrasies and organic disease;" "Because it is cumulative, sacrilegious, an attempt to set aside the decree of Providence, and interferes with Divine justice." All this in the light of the present, seems superstitious and absurd, yet there was this excuse: It was a new remedy. and the habit of theorising without practical demonstration, was much more prevalent forty years ago than now, and facts prove that, owing to the brilliancy of the discovery, there were many exaggerations.

In Vol. I, of the Transactions of the American Med. Association, the Committee on Obstetrics report unqualifiedly that chloroform given in small quantities during confinement, is safe in *all* cases. Up to this time it had been employed in something over 2000 cases without a single untoward result. Dr. Henry Miller believed chloroform the safest and most manageable of all anæsthetics, and if not used to a degree beyond the absolute relief of pain, was wholly unattended by danger.

Anæsthetics in midwifery was urged by some of our most prominent obstetricians as early as 1857, and since that time nearly all have added their approval. Dr. Geo. Johnson, a careful and accurate observer, who has made a study of comparative statistics, shows that the death-rate under chloroform has *not* been increased or convalescence prolonged.

The factor that seemed to do more to influence the progress of obstetrical anæsthesia in Great Britian, was its acceptance by the Queen. when Prince Leopold was born, chloroform being administered with gratifying effects, and with the highest praises from Her Majesty. The great mistake under which those laboured who most opposed the method was, the belief that to annul labour pain, profound anæsthesia was necessary; whereas, all that it is necessary is, so to speak, semi-anæsthesia.

Dr. Miller says that "anæsthesia in natural labour is the greatest boon yet discovered for the relief of suffering womankind." Certain it is that the physician who uses chloroform in natural as well as preternatural labours, will not only be satisfied himself, but will for ever establish himself in the goodwill of his patients.

Chloroform being recognized by our ablest physicians as the best anæsthetic agent for this purpose, it may not be amiss to consider a few of the physiological actions of the drug. It is unnecessary here to describe the three stages of anæsthesia which are laid down in text books. It is important, however, in this connection, to observe that chloroform acts principally on the brain or spinal cord, and lastly, upon the peripheral nerves; acts first upon the lower end of the spinal cord, then the dorsal and the cervical portions in succession, and lastly the brain. It is regularly progressive from below upward, therefore one understands why pain is relieved before consciousness is lost, and that uterine contractions are not interfered with during its proper administration.

Dr. Lusk reported a case in his Obstetrical Clinic, where dangerous symptoms were experienced after deep inspirations from a handkerchief freshly saturated with chloroform placed in a paper cone, which were probably due to the manner of administration rather than the drug itself, for the docter opined the whole trouble arose from crowding the cone down upon the face by the assistant, thus shutting out all air and concentrating the vapor. According to Snow and Simpson's statistics, men are naturally more susceptible to the influence of the drug than are women, in the proportion of two to one, while in the pregnant state there seems to be a peculiar immunity from danger which does not exist in the unimpregnated. I have used chloroform in a little over 225 cases with the most happy results in every instance. I have delivered seven pairs of twins among this number with most flattering success. I feel certain had it not been for chloroform in the following case, the patient would have died. Mrs. B.——æt. twenty-two, primipara. Was called to see her about two weeks before confinement when she was suffering from great dyspnœa. On examination found her with most intense anasarca; urine scanty, colourless, and containing about thirty-three per cent. of albumen: tongue dry and fissured; extreme thirst; temperature 100.6°; pulse 120°; great distress after taking nourishment; bowels constipated. I made an unfavourable prognosis but commenced treatment in the ordinary way—supportive, diuretic, diaphoretic, etc. In ten days her size was reduced so that she had some resemblance to a woman. Confinement took place the night of Sept. 17, '87. The pains began irregularly, and were very aggravating. I began giving chloroform at once, being very apprehensive of convulsions. In less than fifteen minutes the contractions became regular, and increased in intensity, to the great satisfaction of both self and patient. I continued the administration with care until her last baby was born, about nine o'clock the following morning, without a single untoward effect. After putting the patient in as comfortable a condition as possible, I left for home with a more exalted opinion of chloroform than ever before. The following morning I was summoned in haste, the messenger informing me that my patient was in a convulsion. I reached the place as quickly as possible, and at once gave chloroform and bled freely, which soon controlled the convulsions. Then removed the chloroform, when bright spots began soon to appear before her eyes, which admonished us to again resort to the anæsthetic, which was continued for about twenty-four hours, as every time we attempted to remove, symptoms of convulsions reappeared. After that she slowly recovered, and to-day enjoys the pleasurable company of her babies.

I believe that there are very few contra-indications to the use of chloroform in labour, though, of course, when there is severe organic disease of any kind it should be administered with proportionate care. In advanced disease of the lungs statistics prove clearly that the agent can be given with perfect impunity and even with benefit, as is shown in M. Lucas Championniere's case, where he gave it to a woman well advanced in tuberculosis for four hours without intermission; the effects were so delightful that she begged for its continuance, and to gratify her he administered for an hour after the child was born, and without the slightest bad effect. Formerly it was held that if a patient had any heart trouble chloroform could not be tolerated; but it has been scientifically proven that there is but one organic cardiac disease that contra-indicates the use of the drug in parturition, and that, fatty degeneration. But even in this disease Dr. Snow says: "A person is more likely to recover with chloroform, if the pain be severe, than without it." In all valvular disease where chloroform is properly given it is safer than severe pain, not only in obstetrics but in all surgical operations. and causes less disturbance of the heart. Dr. Championniere remarks: "If I recognise an organic affection of the heart without pulmonary complication, I should rather give the chloroform than to let her suffer."

Dr. Verglet Bordeau, a very reliable author, says unqualifiedly: "Disease of the heart is not a contra-indication to the use of anæsthetics!" The most complete and satisfactory study of the question was by Dr. Angus McDonald, in 1878, who published a book entitled, "The Bearings of Chronic Diseases of the Heart upon Pregnancy, Parturition, and Child-birth," in which he says: "If chloroform be properly administered, I think it cannot but be useful in all cases." He also argues, as do most authors, that the straining and suffering is far more dangerous than chloroform properly administered.

Dr. Fordyce Barker says: "Disease of the heart, lungs, or kidneys, is an additional reason for resorting to anæsthesia in midwifery, as the vital forces are thus saved rather than exhausted." And so I might cite you others, but the authority already referred to is certainly all that one can desire. In my experience I have been led to give chloroform almost indiscriminately in labour; and I have never had a case in which I regretted so doing. I never have had a post partum hæmorrhage since I adopted the use of chloroform, save once, and that was in a case I delivered immediately upon entering the house, in which I did not use this agent. Three years laters I attended the same woman and gave chloroform, and there was no hæmorrhage.

I have attended at least a dozen women who before, in confinement, always without chloroform, had post partum hæmorrhage, and suffered no undue flow when the drug was employed. Experience and observation, therefore, teach me that the agent is more likely to be attended without than hæmorrhage, or, in other words, chloroform prevents hæmorrhage by preserving the strength of the patient during labour, which overcomes that muscular exhaustion that is inevitably present in post partum flooding.

I have never attended a single case of confinement with chloroform which was attended with sufficient laceration of the perineum to require operation; therefore, in my judgment, it prevents laceration by causing relaxation of the soft parts. I have also noticed that labour is hastened by giving the agent, and that it is seldom necessary to resort to forceps. Perhaps this can be accounted for in part, at least, because of relief from the pain, the patient being easily induced to assist expulsion. Also, I have noticed many times that when the pains were aggravating and irregular, they were at once intensified and satisfactory on administering chloroform.

The time is fast approaching when it will be as unusual to attend a case of obstetrics without anæsthetics, as it is to-day to amputate a leg without an anæsthetic. Possibly the tenor of this paper may not meet with the approval of all, but it is strictly in accord with the practice and teaching of the most eminent obstetricians of America, England, France, and Germany.

Those who are using anæsthetics in all cases of labour, with rare exceptions, are capturing the confidence of the people, and justly leaving those in the lurch who fail to adopt it.

If I succeed in inducing even one member of the profession who has not previously used chloroform in natural labour to try it, I shall be abundantly remunerated for this paper.

VI.—DISEASES OF THE SKIN.

RECENT ADVANCES IN THE TREATMENT OF DISEASES OF THE SKIN.[1]

By L. Duncan Bulkley, M.D.,

of new york.

In opening the Second Session of the Section of Dermatology and Syphilography of the American Medical Association. I must first express my thanks publicly to the gentlemen who at the last session so kindly called me the second time to preside over your deliberations an honour which was as unexpected as it was gratifying. I must also congratulate you, and, I believe, the profession at large, upon the interest which the Section has developed, and express the hope that by its means the large and important field of study and practice which is here represented may be simplified, so that diseases of the skin may no longer represent the *terra incognita* which they have sometimes been considered by those inexperienced therein.

As was remarked last year, on opening the session, the Section is organised for work in the line of *practical* dermatology, and as a Section of the American Medical Association it should be attended by members who are not dermatologists, and subjects should be presented which are of general and practical interest and value to the general practitioner if we would seek to give the widest usefulness to our Section.

With this aim in view we have this year, as well as last, prepared a "question box" into which any one may drop a written slip regarding any subject upon which he would like aid or information from those present, or on which may be proposed subjects for future discussion. It is earnestly requested that this method of securing an interchange of ideas be utilized to as great a degree as possible; an hour has been set apart on the second day for answering such questions, and further time can be taken later if necessary; if freely used this plan might be made the means of developing very interesting practical matter which would not otherwise be reached.

The general topics assigned for discussion at this session, namely, "The Treatment of Tinea Tonsurans," and "The Indications for and Duration of the Treatment of Syphilis," are, it is thought, subjects which are of very considerable practical and general interest. While pathological considerations, and those relating to rare and peculiar diseases of the skin may be of a certain advantage here, and may more or less find a place in this Section, it is hoped that more common matters, which shall be of use in general practice, may in the main be presented, while the more abstruse and difficult subjects shall be left for the consideration of those whose attention is wholly or largely given to this branch, in the American Dermatological Association.

By the rules of the American Medical Association it is the duty of the Chairman of the various Sections to give an address upon the advances which have been made in the departments of medicine represented by the Sections, and to bring to their attention such matters as may be considered of interest and profit. In accordance with this rule I beg now to direct your attention for a short time to the subject of "Recent Advances in the Treatment of Diseases of the Skin." Inasmuch as this is the first time that this subject has been presented before the Section, we have no date from which we may reckon the *recent* advances in the treatment of diseases of the skin; I have thought it best, therefore, not to confine our considerations to any specified time, but to look over the field a little broadly, and to take account of stock, as it were, endeavouring to discriminate between the good, bad, and indifferent of the more recent so-called "advances" in this department.

It is a constant remark among those acquainted with the subject, that the need is not so much for new remedies, in dermatology, or indeed in any department of medicine, as it is of a better knowledge of the true value and mode of application of those means of combating disease which we now possess. While the question is repeatedly put to one occupied in any special branch, "What is the newest or best remedy for this or that complaint," he is obliged just as frequently to reply that there is no one remedy or plan of treatment which is wholly satisfactory in any particular disease, or which will reach every case; and if perchance, a suggestion is made of any particular drug or method he feels that the chances are very great that there will be some error or failure to use the remedy correctly, and that the ultimate result is very doubtful. In no department of medicine is this true to a greater extent than in diseases of the skin, and yet nowhere can we see more brilliant results, the accuracy and truthfulness of which cannot be denied, because plainly visible to all, than in the department of dermatology.

The first advance, therefore, to which I would call attention in the treatment of diseases of the skin is the recognition of the fact on the part of those acquainted with the subject that accuracy of diagnosis is essential to success in the treatment of this class of affections, and intelligence in the application of remedies can alone insure results which are not disappointing. I should feel like apologizing for such an apparently self-evident statement, were it not that a considerable experience in consultations with other physiclans has made me think that too little care is often spent in studying this class of cases, and in recognizing all the features requiring attention, both as regards the local affection and the constitutional condition of the patient. If the same care and thought were expended upon certain cases of skin disease which are readily given to obstinate or obscure diseases of other organs there would be less difficulty in their management. The time has passed when a patient afflicted with an affection of the skin should at once be given arsenic internally and zinc ointment externally; and then, in the event of probable failure, that he should be given mercury or iodide of potassium, under the suspicion that perhaps there may be some "taint;" and then in the further event of a failure of these plans, that he should be either left to suffer, or be informed that it would be dangerous to cure the skin trouble lest "the disease might strike in." There is much in the practice of dermatology which the general practitioner may readily grasp and use, if only sufficient care and thought be given, and, in my judgment, as remarked before, there is much less need of new remedies than there is of a careful, proper, and widespread knowledge of the means already known, and their intelligent use.

The second point to which I would call your attention is, that while accuracy of diagnosis is the first essential to success, it is almost equally important to consider well and appreciate thoroughly the particular condition or stage of the eruption under consideration, and, knowing the action and effect of each remedy to use it accordingly. The same measure advised for a certain disease will act entirely different under different conditions and at various stages of the complaint, so that one constantly sees harm done from harsh remedies when those of a soothing nature were required, and mild measures are often uselessly employed when those of a stimulating character were demanded. As a corrollary to this we learn that even the new remedies and methods of treatment advanced will often fail of success unless it is known exactly at what stage or condition they were employed, and in what manner they acted.

One more general remark may be added and we will pass to consider some of the more recent advances in dermatology. It is this. Not only do remedies and measures act differently in different persons and under diverse conditions, and in different stages of a disease, but their action may be modified, aided or retarded by a number of influences which are not always thought of, such as diet, hygiene, and the effect of other remedies, internal or external. Therefore, in the use of any newly-recommended measure all other proper adjuvants are to be employed, and all antagonistic elements are to be removed; and as a corrollary to this we learn that new remedies are not always to be judged negatively by an apparent failure, nor, on the other hand, can we always conclude favourably of the effect of any special agent unless all other elements bearing on the case are also duly considered.

With this much of preface we may consider some of the therapeutical elements which have in recent years been introduced into the practice of dermatology. Time will not permit of a full consideration of all that might be mentioned with advantage, much less of the many which have been brought forward whose claims have not been fully substantiated. Indeed, much even that might be of interest and value must be left for my successors in office, who will, no doubt, consider and present the subjects with abler pens than mine.

First, among the advances in dermatology during recent years to be mentioned should be the *mechanical therapy* of diseases of the skin, which, when properly employed, aids very greatly in the management of many conditions which had heretofore proved very rebellious; of this there are several forms. The curette is very serviceable in the treatment of lupus, also in removing small epitheliomata, warts and excrescences, and it may sometimes be used with advantage on chronic patches of eczema, also psoriasis.

The cutaneous punch, as introduced by Keyes[2] is also of value in removing small circular portions of skin, the seat of moles and the like, also powder stains, and likewise in taking sections of diseased tissue for microscopic examination.

The cutaneous lance plays an important part in the treatment of acne, and together with the comedo extractor, will accomplish more for some cases of this disease than weeks or even months of other treatment can effect without them.

Multiple scarification, performed either with a scalpel or an especial knife made for the purpose, with the cutting surface on the end, or with the many-bladed knife of Squire, serves an excellent purpose in certain cases of lupus, and will also yield good results in some nævi, and in

[1] Read in the Section on Dermatology and Syphilography at the Fortieth Annual Meeting of the American Medical Association held at Newport, R.I., June, 1889.

[2] Keyes, Jour. Cutaneous and Genito-Urinary Diseases, vol. v., 1887, p. 98.

rosacea. The large veins of acne rosacea, especially on the nose, may be removed by slitting them up carefully and burning the track of the vein with a point of nitrate of silver. They may also be successfully obliterated by electrolysis.

Electrolysis now plays a considerable part in dermal therapy, and in some conditions yields brilliant results. Its use, now so common, in destroying superfluous hairs, need but be mentioned, as is well known, it offers about the only method of permanently removing this blemish, which often proves such a serious annoyance or distress to those thus afflicted. The only other method known to me is one which I devised and presented some years ago, namely, that of boring out each hair follicle with a three-cornered needle, dipped in carbolic acid; when well performed this is fully as successful as electrolysis, and is preferred by some patients who have had both methods used on them.

Electrolysis is likewise of value in destroying pigmentary and hairy moles, and nævi of various sizes, as also in producing the absorption of tumours. The galvanic cautery also plays an important part in the treatment of some affections, the end, however, being the same as that obtained by the actual cautery and by Pacquelin; but with the galvanic cautery more delicate work can be done, and Besnier has devised a considerable variety of shapes for the knives, some of them having a number of fine points, heated by electricity, for the treatment of nævus and other conditions. The value of the galvanic current, variously applied, must also be reckoned among the advances of recent years. It is most valuable in checking the pain accompanying the following herpes zoster, and there is some evidence that it tends to arrest the progress of the disease; it is valuable in relieving the pain in dermatolgia, and to a certain extent will control pruritis. Galvanization has also been reported on favourably in connection with other diseases of the skin, notably eczema, it being used in the form of general or central galvanization. Faradization has also been recommended in acne rosacea, but is of doubtful value.

Perhaps there are no remedies to which more attention has been been called of late than ichthyol and resorcin, largely through the instrumentality of Dr. Unna, of Hamburg, and time sufficient has now elapsed since their first introduction to allow of judgment regarding their true merits, for quite contradictory reports have appeared concerning them. They are placed by Unna as reducing agents, drawing oxygen from the tissues, and altering the corneous layer of the skin. They are by no means indifferent substances, but while capable of doing more or less good when properly used, they are irritating in many conditions, and in my experience, as also that of some others, they have not fulfilled the expectations excited by Unna's original contributions to the subject.

Ichthyol should always be used weak at first, the strength being increased according to the effect produced; 2 per cent., either in water or ointment, is strong enough to begin with, and rarely will more than 5 per cent. be well borne, at any rate on American skins. As a lotion, 2 to 3 per cent. in water, it certainly often exercises a remarkable effect on ulcers of the leg, they being kept wet with it all the time, the dressing being covered with a thickness of woollen blanket (but not rubber or oil-silk), to prevent too rapid evaporation. It is sometimes well at night to substitute an ointment, with 2 or 3 per cent. of ichthyol and a little zinc oxide. In certain moist eczemas about the folds of the body, a light bathing with a weak, 2 per cent. ichthyol lotion, followed by a calamine and zinc lotion, will give much better results than the latter alone. In certain cases in eczema in infants the effect produced by a thorough and continuous use of a zinc ointment containing 20 grains of ichthyol and 15 or 20 of salicylic acid, is certainly remarkable, and undoubtedly much greater than from either the zinc ointment alone, or when combined only with the salicylic acid.

Time does not permit of a fuller consideration of ichthyol in this place, but enough has been said to show that it is an agent of some importance, capable of doing harm when used too strong, and of moderate value in allaying acute erythematous conditions of the skin.

Resorcin, which has been spoken of much in connection with ichthyol, is said to have much the same effect, but its action is more uncertain, and its use more restricted. It is undoubtedly a parasiticide, and forms a very cleanly and pleasant application in tinea vesicular, used in solution from 3 to 5, or even 10 per cent. in water with a little alcohol and glycerine. It is also of value in tinea circinata and maginatum, and it is claimed that a strong ointment, from 3 to 10 per cent., will act most favourably in tinea sycosis. Resorcin is also serviceable in pityriasis capitis, used in a 3 to 5 per cent. solution with alcohol and castor oil. In seborrhœic eczema it also acts very well in a strength of 3 per cent., with zinc ointment. In psoriasis it may be used considerably stronger, even up to 10 to 20 per cent. in ointment.

Resorcin certainly seems to have considerable effect upon the sebaceous glands, and is useful in many of the forms of acne. Used in an alcoholic and watery solution, of from 2 to 5 per cent, it checks the oily secretion so common on portions of the face, and as an addition to lotions containing sulphur it often aids greatly in the treatment of acne. It must not be forgotten, however, that resorcin may prove very irritating if used in too strong a proportion—3 to 10 per cent. is quite sufficient—and also that it often produces a discoloration of the epidermis, which may take some little time to wear off.

Unna has also, during the past few years, written much concerning the uses of various ointments, made into the form of plasters, by making them thicker and more sticky, and then pressing them upon and into the meshes of muslin; the so-called "pflaster-mulle" have been imported from Germany but little, and are difficult to obtain. They are made to contain zinc, tar, naphthol, chrysarobin, ichthyol, salicylic acid, and other ingredients. These plasters serve a certain valuable purpose in keeping a fixed dressing in localities where it would otherwise be difficult to retain an application, and also by the maceration afforded aid in removing disease; on the other hand, they often prove too drawing, and unless the medicament is very bland, much inflammation may thereby be set up.

In the same line of therapy may be mentioned the "dermatological plasters," now prepared and offered by several firms in this country, which at times serve an excellent purpose; they are mostly made up with rubber plaster, and often prove too heating and drawing, and can hardly be considered the equivalent either of the "pflaster-mulle" or of proper ointments well spread on lint and kept in place by suitable dressings. Among these new plasters may be found those containing very many of the more common and newer drugs used in dermatology. I cannot speak personally regarding very many of these, but some of them prove at times of great service. Thus, in thickened patches of eczema, about the hands and feet especially, the salicylic acid plaster, 10 or 20 per cent., will promote absorption and greatly reduce the thickening; those with zinc and tar, each 10 per cent., are also valuable in eczema, and those with 10 per cent. of chrysarobin act well in psoriasis; all are familiar with the value of plasters containing mercury in reducing the late lesions of syphilis.

Attempts have been made in other directions as to the means of securing fixed dressings on the skin, and various preparations have been brought forward to hold the medicament in solution or suspension, while it is painted over the affected surface. The use of collodion, made flexible with castor oil, has long been known, and this often serves a most excellent purpose when containing from 3 to 5 per cent. of chrysarobin, or pyrogallic acid, and as much salicylic acid; iodine may also be successfully applied in this manner. Gutta-percha dissolved in chloroform, the liquor gutta-perchæ of the Pharmacopœia, or traumaticine, as it has been called by the trade, affords another admirable method of affixing medicaments to the skin; any desired substance, oxide of zinc, bismuth, tannin, chrysarobin, or preparations of mercury may be suspended in it, and made to adhere to the skin thereby.

Another mode of making fixed dressings is that known as glycerine jelly, made by boiling one part of gelatin with three or four of glycerine, and a little water if necessary to make a gelatinous mass. The various ingredients desired are incorporated with this while hot, by stirring, generally from 5 to 10 per cent. being added, together with a little carmine to give a flesh tint if it is to be used on exposed surfaces. This forms a bland dressing, and with zinc or bismuth serves well to protect large surfaces; it will not adhere when there is moisture exuding, but on dry, scaly eczema, in some cases of lichen planus, and pityriasis losea, it forms a serviceable dressing. Carbolic acid, camphor, or cocaine may be adeed to relieve itching. It is applied by placing the jar containing the jelly in hot water, when the liquefied substance can be freely painted over the affected surface, forming a smooth protecting coat as it cools.

Considerable attention has been called to lanolin during the past few years, largely, it is feared, on account of the vigour with which it has been pushed in a mercantile way. Its merits have been pretty well tested, and it may be stated that it has not fulfilled the high expectations which have been raised concerning it; it has its value and its applications, but they are limited, and it will undoubtedly take its proper place among the remedies which are of value in the treatment of diseases of the skin. It does not answer alone as a basis for ointments, but when combined with other fatty ingredients, in about 25 per cent., it often aids in keeping the skin soft and pliable, when without it the oily matter would disappear and leave the surface harsh. It has been advocated largely on account of its supposed power of inducing absorption of the medicament which it contained; if this power existed in this substance alone, it would not recommend it for universal use, for in much of dermal therapeutics, the object is not to secure absorption of remedies, but to act on the outer surface. It would surprise many to see how very little it is used by those engaged in the practice of dermatology.

The Spirit of the Societies.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.[1]

ON MUSEUMS.

The president dealt with two subjects—Museums, their arrangement and utility; and the laws which regulate the evolution of organic beings. In considering the former, he said there could be no doubt that among the various methods by which the aims of the British Association may be brought about, the collection and preservation of objects available for examination, study, and reference—in fact, the formation of what are now called museums—was one of very great practical importance. It was a subject still little understood, though fortunately beginning to attract attention. A committee of members of the Association was at the present time engaged in collecting evidence upon it, and had issued some valuable reports. During the present year an asssociation of curators and others interested in museums had been founded for the purpose of interchange of ideas upon the organisation and management of these institutions. It was a subject, moreover, which had more than any other occupied his time and attention almost from the earliest period of his recollection, and it was in the hope of helping on or guiding the movement that he selected the subject.

THE ESTABLISHMENT OF A MUSEUM.

The first consideration in establishing a museum, large or small, either in a town, institution, society, or school, was that it should have some definite object or purpose to fulfil; and the next, that means should be forthcoming not only to establish, but also to maintain the museum in a suitable manner to fulfil that purpose. Some persons were enthusiastic enough to think that a museum was in itself so good an object that they had only to provide a building and cases and a certain number of specimens, no matter exactly what, to fill them, and then the thing was done; whereas, the truth was, the work had only then begun. What a museum really depended upon for its success and usefulness was not its building, nor its cases, not even its specimens, but its curator. He and his staff were the life and soul of the institution, upon whom its whole value depended, and yet in many they were the last to be thought of. The care, the preservation, the naming of the specimens, were either left to voluntary effort—excellent often for special collections and for a limited time, but never to be depended on as a permanent arrangement—or a grievously under-salaried and consequently uneducated official was expected to keep in order, to clean, dust, arrange, name, and display in a manner which would contribute to the advancement of scientific knowledge, collections ranging in extent over almost every branch of human learning, from the contents of an ancient British barrow to the last discovered bird of paradise from New Guinea.

PRECIOUS OBJECTS REALLY THROWN AWAY.

Valuable specimens not unfrequently found their way into museums thus managed. Their public-spirited owners fondly imagined that they would be preserved and made of use to the world if once given to such an institution. Their fate was, unfortunately, far otherwise. Dirty, neglected, without label, their identity lost, they were often finally devoured by insects or cleared away to make room on the crowded shelves for the new donation of some fresh patron. It would be far better that such museums should never be founded. They were traps into which precious—sometimes priceless—objects fell only to be destroyed; and, what was still worse, they brought discredit on all similar institutions, made the very name of museum a byword and a reproach, hindering instead of advancing the recognition of their value as agents in the great educational movement of the age. A museum was like a living organism—it required continual and tender care. It must grow, or it would perish; and the cost and labour required to maintain it in a state of vitality were not yet by any means fully realised or provided for, either in our great national establishments or in our smaller local institutions.

THE OBJECTS TO BE ATTAINED.

The real objects of forming collections were two, quite distinct, and sometimes even conflicting. The first was to advance or increase the knowledge of some given subject. This was generally the motive of the individual collector, whose experience showed him the vast assistance in forming definite ideas in any line of research in which he might be occupied that might be derived from having the materials for its study at his own command, to hold and to handle, to examine and compare, to take up and lay aside whenever the favourable moment to do so occurred. But unless his subject was a very limited one, or his means the reverse, he soon found the necessity of consulting collections based on a larger scale than his own.

WHAT THE NATURALIST REQUIRES.

Very few people had any idea of the multiplicity of specimens required for the purpose of working out many of the simplest problems concerning the life history of animals or plants. The naturalist had frequently to ransack all the museums, both public and private, of Europe and America in the endeavour to compose a monograph of a single common genus, or even species, that should include all questions of its variation, changes in different seasons, and under different climates and conditions of existence, and the distribution in space and time of all its modifications. He often had to confess at the end that he had been baffled in his research for want of the requisite materials for such an undertaking. Of course this ought not to be, and the time would come when it would not be, but that time was very far off yet.

WHAT THE PUBLIC NEED.

But there was another and a far larger class to whom museums were, or should be, a powerful means of aid in acquiring knowledge. Among such, those who were commencing more serious studies might be included; and he especially referred to the much more numerous class who, without having the time, the opportunities, or the abilities to make a profound study of any branch of science, yet took a general interest in its progress, and wished to possess some knowledge of the world around them, and of the principal facts ascertained with regard to it, or at least some portions of it. For such persons museums might be, when well organised and arranged, of benefit to a degree that at present could scarcely be realised. To diffuse knowledge among persons of this class was the second of the two purposes of museums. The main cause of what might be fairly termed the failure of the majorty of museums—especially museums of natural history—to perform the functions that might be legitimately expected of them, was that they nearly always confound together the two distinct objects which they might fulfil, and by attempting to combine both in the same exhibition practically accomplished neither.

WHAT IS THE MAIN END OF THE MUSEUM?

In accordance with which of those two objects was the main end of the museum, so should the whole be primarily arranged; and in accordance with the object for which each specimen was required, so should it be treated. The specimens kept for research, for the advancement of knowledge, for careful investigation in structure and development, or for showing the minute distinction which must be studied in working out the problems connected with variations of species according to age, sex, season, or locality; for fixing the limits of geographical distribution, or determining the range in geological time, must be not only numerous (so numerous, indeed, that it was almost impossible to put a limit on what might be required for such purposes), but they must also be kept under such conditions as to admit of ready and close examination and comparison. If the whole of the specimens really required for enlarging the boundaries of zoological or botanical science were to be displayed in such a manner that each one could be distinctly seen by any visitor sauntering through the public galleries of a museum, the vastness and expense of the institution would be out of all proportion to its utility; the specimens themselves would be quite inaccessible to the examination of all those capable of deriving instruction from them, and, owing to the injurious effects of continued exposure to light upon the greater number of preserved natural objects, would ultimately lose a large part of their permanent value. Collections of this kind must, in fact, be treated as the books in a library, and be used only for consultation and reference by those who were able to read and appreciate their contents.

COLLECTIONS DESIGNED FOR RESEARCH.

In the arrangement of collections designed for research, which, of course, would contain all those precious specimens called "types," which must be appealed to through all time to determine the species to which a name was originally given, the principal points to be aimed at were the preservation of the objects from all influences deleterious to them, especially dust, light, and damp; their absolutely correct identification and record of every circumstance that need be known of their history, their classification and storage in such a manner that each one could be found without difficulty or loss of time; and, both on account of expense as well as convenience of access, they should be made to occupy as small a space as was compatible with those requirements. They should be kept in rooms provided with suitable tables and good light for their examination, and within reach of the necessary books of reference on the particular subjects which the specimens illustrate. Furthermore, the rooms should be so situated

[1] Abstract of Presidential Address by Professor William H. Flower.

that the officers of the museum, without too great hindrance to their own work, could be at hand for occasional assistance and supervision of the student, and if collections of research and exhibited specimens were contained in one building it was obvious that the closer the contiguity in which those of any particular group were placed the greater would be the convenience both for students and curators, for in very few establishments would it be possible to form each series on such a scale as to be entirely independent of the other.

COLLECTIONS ARRANGED FOR INSTRUCTION.

On the other hand, in a collection arranged for the instruction of the general visitors, the conditions under which the specimens were kept should be totally different. In the first place, their numbers must be strictly limited, according to the nature of the subjects to be illustrated and the space available. None must be placed too high or too low for ready examination. There must be no crowding of specimens one behind the other, every one being perfectly and distinctly seen, and with a clear space around it. Every specimen exhibited should be good of its kind, and all available skill and care should be spent upon its preservation and rendering it capable of teaching the lesson it is intended to convey. And here he could not refrain from saying a word upon the sadly neglected art of taxidermy, which continued to fill the cases of most of our museums with wretched and repulsive caricatures of mammals and birds, out of all natural proportions, shrunken here and bloated there, and in attitudes absolutely impossible for the creature to have assumed while alive. Taxidermy was an art resembling that of the painter, or rather the sculptor; it required natural genius as well as great cultivation, and it could never be permanently improved until we had abandoned the present conventional low standard and low payment for "bird-stuffing," which was utterly inadequate to induce any man of capacity to devote himself to it as a profession. Every specimen exhibited should have its definite purpose, and no absolute duplicate should on any account be permitted. Above all, the purpose for which each specimen was exhibited, and the main lesson to be derived from it, must be distinctly indicated by the labels affixed, both as headings of the various divisions of the series, and to the individual specimens. A well-arranged educational museum had been defined as a collection of instructive labels illustrated by well-selected specimens.

THE ORDER TO BE OBSERVED.

What was, or should be, the order of events in arranging a portion of a public musuem? Not, certainly, as too often happened now, bringing a number of specimens together almost by haphazard, and cramming them as closely as possible in a case far too small to hold them, and with little reference to their order or to the possibility of their being distinctly seen. The curator must carefully consider the object of the museum, the class and capacities of the persons for whose instruction it was founded, and the space available to carry out this object. He would then divide the subject to be illustrated into groups, and consider their relative proportions, according to which he would plan out the space. Large labels would next be prepared for the principal headings, as the chapters of a book, and smaller ones for the various subdivisions. Certain propositions to be illustrated, either in the structure, classification, geographical distribution, geological position, habits, or evolution of the subjects dealt with, would be laid down and reduced to definite and concise language. Lastly would come the illustrative specimens, each of which as procured and prepared would fall into its appropriate place. As it was not always easy to obtain these at the time that they were wanted, gaps would often have to be left; but those, if properly utilised by drawings or labels, might be made nearly as useful as if occupied by the actual specimens. A public exhibition which was intended to be instructive and interesting must never be crowded. Every such exhibition, whether on a large or small scale, could only contain a representative series of specimens, selected with a view to the needs of the particular class of persons who were likely to visit the gallery, and the number of specimens exhibited should be adapted to the space available.

THE PUBLIC MUSEUMS OF THE FUTURE.

The ideal public museums of the future would, however, require far more exhibition space than had hitherto been allowed; for though the number of specimens shown might be fewer than was often thought necessary now, each would require more room if the conditions above described were carried out, and especially if it was thought desirable to show it in such a manner as to enable the visitors to realise something of the wonderful complexity of the adaptations which bring each species into harmonious relation with its surrounding conditions. Artistic reproductions of natural environments, illustrations of protective resemblances, or of special modes of life, all required much room for their display. This method of exhibition, wherever faithfully carried out, was, however, proving both instructive and attractive, and would doubtless be greatly extended. As the actual comparison of specimens was the basis of zoological and botanical research, and as work done with imperfect materials was necessarily imperfect in itself, it was far the wisest policy to concentrate in a few great central institutions, the number and situation of which must be determined by the population and the resources of the country, all the collections, especially those containing specimens already alluded to as so dear to the systematic naturalist, known as author's "type," required for original investigations. It is far more advantageous to the investigator to go to such a collection and take up his temporary abode there, while his research was being carried out, with all the material required at his hand at once, than to travel from place to place and pick up piecemeal the information he required, without opportunity of direct comparison of specimens. A local collection, illustrating the fauna and flora of the district, should be part of every such museum; and this might be carried to almost any amount of detail, and therefore in many cases it would be very unadvisable to exhibit the whole of it. A selection of the most important objects might be shown under the conditions described above, and the remainder carefully preserved in cabinets for the study of specialists.

EVOLUTION.

Coming to his other topic, the laws which regulate the evolution of organic beings, problems which agitate the minds of all biologists of the present day, he briefly pointed out the nature of the problems and the lines which the endeavour to solve them would probably take. He said—I think I may safely premise that few, if any, original workers at any branch of biology appear now to entertain serious doubt about the general truth of the doctrine that all existing forms of life have been derived from other forms by a process of descent with modification, and it is generally acknowledged that to the records of the past history of life upon the earth we must look for the actual confirmation of the truth of a doctrine which accords so strongly with all we know of the present history of living beings. Professor Huxley wrote in 1875: "The only perfectly safe foundation for the doctrine of evolution lies in the historical, or rather archæological, evidence that particular organisms have arisen by the gradual modification of their predecessors, which is furnished by fossil remains. That evidence is daily increasing in amount and in weight, and it is to be hoped that the comparisons of the actual pedigree of these organisms with the phenomena of their development may furnish some criterion by which the validity of phylogenic conclusions deducted from the facts of embryology alone may be satisfactorily tested."

THE GRADUAL MODIFICATION OF LIVING FORMS.

Palæontology, however, as we all know, reveals her secrets with no open hand. How can we be reminded of this more forcibly than by the discovery, announced scarcely three months ago, by Professor March, of numerous mammalian remains from formations of the Cretaceous period, the absence of which had so long been a source of difficulty to all zoologists? What vistas does this discovery open of future possibilities, and what thorough discredit, if any were needed, does it throw on the value of negative evidence in such matters! Bearing fully in mind the necessary imperfection of the record we have to deal with, I think that no one taking an impartial survey of the recent progress of palæontological discovery can doubt that the evidence in favour of a gradual modification of living forms is still steadily increasing. Any regular progressive series of changes of structure coinciding with changes in time can, of course, only be expected to be preserved and to come again before our eyes under such a favourable combination of circumstances as must be of most rare occurrence; but the links, more or less perfect, of many such series are continually being revealed, and the discovery of a single intermediate form is often of immense interest as indicating the path along which the modification from one apparently distinct form to another may have taken place. Though palæontology may be appealed to in support of the conclusion that modifications have taken place as time advanced, it can scarcely afford any help in solving the more difficult problems which still remain as to the methods by which the changes have been brought about. Ever since the publication of what has been truly described as the "creation of modern natural history," Darwin's work on the "Origin of Species," there has been no little controversy as to how far all the modifications of living forms can be accounted for by the principle of natural selection or preservation of variations best adapted for their surrounding conditions, or whether any, and if so what, other factors have taken part in the process of organic evolution.

A TENDENCY TO VARY.

It is generally recognised that it is one of the main elements of Darwin's, as well as of every other theory of evolution, that there is in every individual organic being an innate tendency to vary from the standard of its predecessors, but that this tendency is usually kept

under the sternest control by the opposite tendency to resemble them, a force to which the terms "heredity" and "atavism" are applied. The causes of this initial tendency to vary, as well as those of its limits and prevailing direction, and the circumstances which favour its occasional bursting through the constraining principle of heredity, offer an endless field for speculation. Though several theories of variation have been suggested, I think that no one would venture to say we have passed beyond the threshold of knowledge of the subject at present. Taking for granted, however, as we all do, that this tendency to individual variation exists, then comes the question, What are the agents by which, when it has asserted itself, it is controlled or directed in such a manner as to produce the permanent, or apparently permanent, modifications of organic structures which we see around us? Is "survival of the fittest," or preservation by natural selection of those variations, best adapted for their surrounding conditions (the essentially Darwinian or still more essentially Wallacian doctrine) the sole or even the chief of these agents? Can isolation, or the revived Lamarckian view of the direct action of the environment, or the effects of use or disuse accumulating through generations, either singly or combined, account for all; or is it necessary to invoke the aid of any of the numerous subsidiary methods of selection which have been suggested as factors in bringing about the great result? Any one who has closely followed these discussions, especially those bearing most directly upon what is generally regarded as the most important factor of evolution—natural selection, or "survival of the fittest"—cannot fail to have noticed the appeal constantly made to the advantage, the utility, or otherwise of special organs or modifications of organs or structures to their possessors. Those who have convinced themselves of the universal application of the doctrine of natural selection, hold that every particular structure or modification of structure must be of utility to the animal or plant in which it occurs, or to some ancestor of that animal or plant, otherwise it could not have come into existence; the only reservation being for cases which are explained by the principle which Darwin called "correlation of growth." Thus the extreme natural selectionists and the old-fashioned school of teleologists are so far in agreement.

ARE CERTAIN STRUCTURES MANIFESTLY USELESS?

On the other hand, it is held by some that numerous structures and modification of structures are met with in nature which are manifestly useless; it is even confidently stated that there are many which are positively injurious to their possessor, and therefore could not possibly have resulted from the action of natural selection of favourable variations. Organs or modifications when in an incipient condition are especially quoted as bearing upon this difficulty. But here, it seems to me, we are continually appealing to a criterion by which to test our theories of which we know far too little, and this (though often relied upon as the strongest) is, in reality, the weakest point of the whole discussion. Of the variations of the form and structure of organic bodies we are beginning to know something, Our museums, when more complete and better organised, will teach us much on this branch of the subject. They will show us the infinite and wonderful and apparently capricious modifications of form, colour, and of texture, to which every most minute portion of the organisation of the innumerable creatures which people the earth is subject. They will show us examples of marvellously complicated and delicate arrangements of organs and tissues in many of what we consider as almost the lowest and most imperfectly organised groups of beings with which we are acquainted. But as to the use of all these structures and modifications in the economy of the creatures that possess them, we know, I may almost say, nothing, and our museums will never teach us these things. If time permitted I might give numerous examples in the most familiar of all animals, whose habits and actions are matters of daily observation, with whose life-history we are as well acquainted almost as we are of our own, of structures the purposes of which are still most doubtful. There are many such even in the composition of our own bodies. How, then, can we expect to answer such questions when they relate to animals known to us only by dead specimens, or by the most transient glimpses of the living in a state of nature, or when kept under the most unnatural conditions in confinement? And yet this is actually the state of our knowledge of the vast majority of the myriads of living beings which inhabit the earth. How can we, with our limited powers of observation, and limited capacity of imagination, venture to pronounce an opinion as to the fitness or unfitness for its complex surroundings of some peculiar modification of structure found in some strange animal dredged up from the abysses of the ocean, or which passes its life in the dim seclusion of some tropical forest, and into the essential conditions of whose existence we have at present no possible means of putting ourselves in any sort of relation? How true it is that, as Sir John Lubbock says, "we find in animals complex organs of sense richly supplied with nerves, but the functions of which we are as yet powerless to explain. There may be fifty other senses as different from ours as sound is from sight; and even within the boundaries of our own senses there may be endless sounds which we cannot hear, and colours as different as red from green of which we have no conception. These and a thousand other questions remain for solution. The familiar world which surrounds us may be a totally different place to other animals. To them it may be full of music which we cannot hear, of colour which we cannot see, of sensations which we cannot conceive." The fact is, that nearly all attempts to assign purposes to the varied structures of animals are the merest guesses and assumptions. The writers on natural history of the early part of the present century, who "for every why must have a wherefore," abound in these guesses, which wider knowledge shows to be untenable. Many of the arguments for or against natural selection, based upon the assumed utility or equally assumed uselessness of animal and vegetable structures, have nothing more to recommend them. In fact, to say that any part of the organisation of an animal or plant, or any habit of instinct with which it is endowed, is useless, or even injurious, seems to me an assumption which, in our present state of knowledge, we are not warranted in making. The time may come when we shall have more light, but infinite patience and infinite labour are required before we shall be in a position to speak dogmatically on these mysteries of nature—labour not only in museums, laboratories, and dissecting rooms, but in the homes and haunts of the animals themselves, watching and noting their ways amid their natural surroundings, by which means alone we can endeavour to penetrate the secrets of their life history. But until that time comes, though we may not be quite tempted to echo the despairing cry of the poet, "Behold, we know not anything," a frank confession of ignorance is the most straightforward, indeed the only honest position we can assume when questioned on these subjects. However much we may be convinced of the supreme value of scientific methods of observations and of reasoning, both as mental training of the individual and in the elucidation of truth and advancement of knowledge generally, it is impossible to be blind to the fact that we are engaged with the investigation of those subjects which are commonly accepted as belonging to the domain of physical science are unfortunately not always, by virtue of being so occupied, possessed of that most precious gift "a right judgment in all things." No one intimately acquainted with the laborious and wavering steps of scientific progress (I can answer at least for one branch of it) can look upon that progress with a perfect feeling of satisfaction. Can it be said of any of us that our observations are always accurate, the materials on which they are based always sufficient, our reasoning always sound, our conclusions always ligitimate? Is there any subject, however limited, of which our knowledge can be said to have reached finality? For myself, I must own that when I endeavour to look beyond the glass, and frame some idea of the plan upon which all the diversity in the organic world has been brought about, I see the strongest grounds for the belief, difficult as it sometimes is in the face of the strange, incomprehensible, apparent defects in structure, and the far stranger, weird, ruthless savagery of habit, often brought to light by the study of the ways of living creatures, that natural selection, or survival of the fittest, has, among other agencies, played a most important part in the production of the present condition of the organic world, and that it is a universally acting and beneficent force continually tending towards the perfection of the individual, of the race, and of the whole living world. I can even go further, and allow my dream still thus to run—

"Oh, yet we trust that somehow good
Will be the final goal of ill—
That nothing walks with aimless feet,
That not one life shall be destroyed
Or cast as rubbish to the void
When God hath made the pile complete.

* * * *

SECTION OF BIOLOGY.

President's Address.—At the first meeting of the section on Thursday, September 12th, the President (Professor J. S. Burdon Sanderson) was prevented by illness from being present. His address was accordingly read by Canon Tristram, one of the Vice-Presidents. In it Dr. Burdon Sanderson said it had long ceased to be possible in the course of an annual address to give an account even of the most important advances made in biology during the preceding twelve months. This was due partly to the vast dimensions of each of the various branches of knowledge included under the term biology, and partly to the increasing divergence between morphology and physiology. From this sundering of sciences which were till recently intimately united physiology chiefly suffered. The physiologist had first to determine what were the chemical and physical endowments of living matter in general, and of each of the varieties thereof which

constituted the animal and plant organism in particular. Then he had to determine how these processes were localised so as to constitute the special function of each structure, and the relation between structure and function in each case. Physiology first studied man and the higher animals, and proceeded to the higher plants, then to invertebrates and cryptogams, ending where development began. From the beginning, her aim had been to correlate function with structure, the principle being that every appreciable difference of structure corresponded to a difference of function; and, inversely, that each endowment of a living organ must be explained as springing from its structure. As function was more complicated than structure, the result of that method must be to bring investigators face to face with functional differences which had no structural differences to explain them. They would in each case come to this issue—plurality of function with unity of structure, the unity being represented by a simple structural element, whether it was retinal cone or cell, possessed of numerous endowments. Structure must at that point cease to be a guide, and two alternatives were then open, namely, to fall back on "that worn out *deux ex machinâ* protoplasm," as if it afforded an explanation of everything which could not be explained otherwise; or to use analyses of function as a guide to the ultra-microscopical analysis of structure. The first of these courses was wrong, the second right, for in following it the fundamental principal was still adhered to that living material acted by virtue of its structure, using that term in a sense which carried it beyond the knowledge that could be gained either by the scalpel or the microscope. It might be anticipated that the future of physiology would differ from the past chiefly in this respect—that histology, once the guide of physiology, had now become her handmaid. The President went on to say that the questions which at present most urgently demanded solution in physiology were those relating to the endowments of apparently structureless living matter. With this view, what had to be done was first to select those cases in which the vital process offered itself in its simplest form; and secondly, to inquire how far in these particular instances—under the guidance of that fundamental principle, the correlation of structure with function, of mechanism with action—inferences might be drawn as to the mechanism by which these vital processes were carried out. The most distinctive property of living matter as compared with non-living was that it was ever changing while ever the same; in other words, life was a ceaseless change. Two kinds of change must be distinguished, both equally characteristic of living organisms—namely, those of growth and decay, and those of nutrition. Growth belonged rather to morphology, and he proposed to speak only of the other kind of change which included all other vital phenomena. The term "nutrition" expressed this very inadequately. "Exchange of material" had been used for half a century to designate the sum of the non-developmental activities of an organism; for this Professor Foster had given the very acceptable substitute, "metabolism." Seen from the morphological point of view, the whole plant and animal kingdom constituted the unfolding of a structural plan which had been once latent in the form of living material of great apparent simplicity. From the physiological side, this apparently simple material was seen to be capable of the discharge of functions of great complexity, and therefore must possess corresponding complexity of mechanism. It was the nature of this invisible mechanism that philosophy thirsty to know. Although little progress had yet been made, the existing knowledge of the subject had so far taken consistent form in the minds of the leaders of physiological thought, that it was possible to distinguish the direction in which the soberest speculation was tending. The non-developmental vital functions of protoplasm were the absorption of oxygen, the discharge of carbon dioxide and water and ammonia, the doing of mechanical work, the production of heat, light, and electricity. All these, except the last, were known to have chemical actions as their inseparable concomitants. The president next discussed the relation of oxygen to living matter and vital process, and went on to say that the word "life" was used in physiology in a technical sense, as denoting a state of change with permanence. In this restricted sense the question "What is life?" was one to which the answer was approachable; but in a higher sense—higher because it appealed to higher faculties in our nature—the word suggested something outside of mechanism, which might perchance be its cause rather than its effect. Thirty years ago the discovery of the cell as the basis of vital function was new, and the mystery which before belonged to the organism was transferred to the unit, which, while it served to explain everything, was itself unexplained. The discovery of the cell seemed to be a very close approach to the mechanism of life; but now they were striving to get even closer, and with the same result. If what he had said was true, there was little ground for apprehension that the habit of scrutinising the mechanism of life tended to make men regard what could be learned as the only kind of knowledge. The tendency was certainly rather in the other direction. What had to be guarded against was the mixing of two methods, and, so far as physiologists were concerned, the intrusion into their subject of philosophical speculation. "Let us, said Dr. Burdon Sanderson in conclusion, "willingly and with our hearts do homage to 'divine philosophy,' but let that homage be rendered outside the limits of our science. Let us, if we are so inclined, cross the frontier and philosophise; but for my part, as a physiologist, I feel more disposed to do my best to furnish professed philosophers with such facts relating to structure and mechanism as may serve them as aids in the investigation of those deeper problems which concern man's relations to the past, the present, and the unknown future.

SECTION OF ANTHROPOLOGY.

Examinations in Bodily Efficiency.—The proceedings in this Section commenced with the reading of a paper read by Mr. Francis Galton, F.R.S., "On the Advisability of Assigning Marks for Bodily Efficiency in the Examinations of Candidates for the Public Services." Mr. Galton said he did not refer in any way to the pass examinations now made by medical men in order to eliminate candidates who were physically unfit. The reform asked for was to give additional marks to those youths who, being fit for service, were at the same time exceptionally well fit so far as bodily efficiency was concerned. The view that literary examinations were indirect tests of bodily efficiency could be shown to be erroneous. Various measurements of Cambridge students had been made during the last two or three years by Dr. Venn, F.R.S. The number of those who were measured was 1,095, and they were divided into three classes—(1) high-honour men; (2) low-honour men; (3) poll men—that was to say, those who did not compete for honours, but took an ordinary pass degree, The result was that the physical efficiency of the three classes proved to be almost exactly the same, except that there appeared to be a slight deficiency in eyesight among the high-honour men. Otherwise they were alike throughout: alike in their average bodily efficiency, and alike in the frequency with which different degrees of bodily efficiency were distributed among them. It seemed, therefore, to be most reasonable whenever two candidates were almost on a par intellectually, though one was superior physically, that the latter should be preferred. The tests would include measures of strength, breathing capacity, agility or promptness, keenness of eyesight and of hearing. Mr. Galton also read a paper "On the Principle and Methods of Assigning Marks for Bodily Efficiency," in which he gave details of the mode of physical examination proposed.

President's Address.—The President, Sir William Turner, M.B., F.R.S., Professor of Anatomy in the University of Edinburgh, then delivered an address on "Heredity." After some introductory remarks, he said that by heredity he meant that special property through which the peculiarities of an organism were transmitted to its descendants throughout successive generations, so that the offspring, in their main features, resembled their parents. The first aspect of the question which had to be determined was whether any physical basis could be found for heredity. Was there any evidence that the two parents contributed each a portion of its substance to the production of the offspring, so as to establish a physical continuity between successive generations? The careful study, especially during the last few years, of the development of a number of species of animals mostly, but not exclusively, among the invertebrata, had established the fact that the young animal arose by the fusion within the egg or germ-cell of an extremely minute particle derived from the male parent, with an almost equally minute particle derived from the germ-cell produced by the female parent. These particles were technically termed in the former case the male pronucleus, in the latter the female pronucleus, and the body formed by their fusion was called the segmentation nucleus. It required the higher powers of the best microscopes to see these nuclei and follow out the process of conjugation. The pronuclei and the segmentation nucleus were, however, complex both in chemical and molecular structure. From the segmentation nucleus produced by the fusion of the pronuclei with each other, and from corresponding changes which occurred in the protoplasm of the egg which surrounded it, other cells arose by a process of division, and these in their turn also multiplied by division. These cells arranged themselves in course of time into layers, which were termed the germinal or embryonic layers. From these layers arose all the tissues and organs of the body, both in its embryonic and adult stages of life. The starting point of each individual organism—that is, of each new generation—was therefore the segmentation nucleus. Every cell in the adult body was derived by descent from that nucleus through repeated division. As the segmentation nucleus was formed by the fusion of material derived from both parents, a physical continuity was established between parents and offspring. But this physical continuity carried with it certain properties which caused the offspring to reproduce

not only the bodily configuration of the parent, but other characters. In the case of man, along with the family likeness in form and features, there was a correspondence in temperament and disposition, in the habits and mode of life, and sometimes in the tendency to particular diseases. By the continual process of division of the cells the substance of the segmentation nucleus was diffused throughout the body of the new individual produced through its influence, so that each cell contained but an infinitesimal particle of it. The parental dilution, if he might say so, was so attenuated as to surpass the imagination of even the most credulous believer in the attenuation of drugs by dilution; and yet these particles were sufficient to stamp the character of the parents, of the grandparents, and of still more remote ancestors on the offspring, and to preserve them throughout life. It was not every cell in the body that could act as a centre of reproduction for a new generation; certain cells, named "germ-cells" and "sperm-cells," were set aside for that purpose. These cells, destined for the production of the next generation, formed but a small proportion of the body of the animal in which they were situated. They were, as a rule, marked off from the rest of the cells of its body at an early period of development. The exact stage at which they became specially differentiated for reproductive purposes varied, however, in different organisms. The germ-cells, after their isolation, took no part in the growth of the organism in which they arose, and their chief association with the other cells of its body was that certain of the latter were of service in their nutrition. The problem, therefore, for consideration was the mode in which these germ or reproductive cells became influenced, so that after being isolated from the cells which made up the bulk of the body of the parent, they would transmit to the offspring the characters of the parent organism. After referring to the theories of Darwin and F. Galton on the subject, Professor Turner said that intimately associated with the conception of heredity was that of variability. Heredity might be defined as the perpetuation of the like; variability as the production of the unlike. It might be asked, Was it possible to offer any feasible explanation of the mode in which variations in organic structure took their rise in the course of development of an individual organism? Certain facts might be adduced as offering a basis for the construction of an hypothesis. Prior to the conjugation of the male and female pronuclei to form the segmentation nucleus a portion of the germ-plasm was extruded from the egg to form what were called the polar bodies. Weismann explained this curious phenomenon on the hypothesis that a reduction of the number of ancestral germ-plasms in the nucleus of the egg was a necessary preparation for fertilisation, and for the development of the young animal. He supposed that by the expulsion of the polar bodies one-half the number of ancestral germ-plasms was removed, and that the original bulk was restored by the addition of the male pronucleus to that which remained. As precisely corresponding molecules of this plasm need not be expelled from each ovum, similar ancestral plasms were not retained in each case; so that the diversities would arise even in the same generation and between the offspring of the same parents. The segmentation nucleus was not a homogeneous structureless body, but was built up of different parts. Most noteworthy were the extremely delicate threads or fibrils, called chromatin filaments, which were either coiled on each other or intersected to form a network-like arrangement. In the meshes of this network a viscous—and, so far as was yet known, structureless—substance was situated. Before the process of division began in the segmentation nucleus these filaments swelled up and then proceeded to arrange themselves at first into one and then into two star-like figures before the actual division of the nucleus took place. It was obvious, therefore, that the molecules which entered into the formation of the segmentation nucleus could move within its substance, and undergo a readjustment in size, and form, and position. But this readjustment of material without doubt applied to the entire molecular structure of the segmentation nucleus. As the cells of the embryo, from which all the tissues and organs of the adult body were derived, were themselves descendants of the segmentations nuclei they would doubtless inherit from it both the power of transmitting definite characters and a certain capacity for readjustment both of their constituent materials and their relative positions towards each other. One might conceive, therefore, that if in a succession of organisms derived common ancestors the molecular particles were to be of the same composition and to arrange themselves in the segmentation nucleus and in the cells derived from it on the same lines, these successive generations would be alike; but if the lines of adjustment and the molecular constitution were to vary in the different generations, then the products would not be quite the same. Variations in structure, and to some extent also in the construction of parts, would arise, and the unlike would be produced. Moreover, in the higher organisms, and in multicellular organisms generally, an individual was derived, not from one parent only, but from two. Weismann emphasized this combination as the cause of the production of variations and the transmission of hereditary individual characters. If the proportion of the particles derived from each parent and the forces which they exercised were precisely the same in any individual case, then one could conceive that the product would be a mean of the components provided by the two parents. But if one parent were to contribute a larger proportion than the other to the formation of a particular organism, then the balance would be disturbed, the offspring in its character would incline more to one parent than to the other, according to the proportion contributed by each, and a greater scope for the production of variations would be provided. These differences would be increased in number in the course of generations, owing to new combinations of individual characters arising in each generation. As variations, when once they had arisen, might be hereditarily transmitted, the Darwinian theory might be defined as heredity modified by variability. Many variations which might arise in the development of an individual, and which were of service to that individual, would tend to be preserved and perpetuated in its offspring by hereditary transmission. On the other hand, variations which were useless or even detrimental to the individual were also capable of being hereditarily transmitted. Several striking instances of congenital defect or malformation thus handed down from generation to generation were adduced, and the transmission of a tendency to particular disease, such as tuberculosis, cancer, gout, rheumatism, and hæmophilia, was alluded to. In the transmission of deformity or disease, consanguinity in the parents was an important, though by no means constant, factor.

If both parents were physiologically perfect, it might be expected that the offspring would also be so, but should both be physiologically imperfect, it might be anticipated that the imperfections, if of a like nature, would be intensfied in the children. In this lay the risk of consanguineous marriages, for no family could lay claim to physiological perfection. With reference to the transmissibility of characters which had been "acquired" by the parent, that term had not always been used with the same signification. In its wider meaning it might cover all the characters which made their first appearance in an individual, and which were not found in its parents, in whatever way they had arisen; first, whether their origin were due to such molecular changes in the germ-plasm as might be called spontaneous, leading to such an alteration in its character as might produce a new variation; or, secondly, whether their origin were accidental, or due to habits, or to the nature of the surroundings, such as climate, food, etc. Characters produced in the germ-plasm itself and all other characters resulting from this latter cause, Weismann named "blastogenic;" characters first appearing in the body itself and following from the reaction of the soma under direct external influences, he termed "somatogenic," and he suggested that to those the term "acquired characters" should be restricted. Under the latter head were included the effects of mutilation, the changes which followed from increased or diminished performance of function, those directly due to nutrition, etc. Weissmann maintained that all blastogenic characters could be transmitted, while the somatogenic could not. Sir William Turner agreed with much that had been said by Weismann, as to the want of sufficient evidence to prove that mutilation in the parent could be transmitted to the offspring. He would, however, search for illustrations of the transmission of somatogenic characters in the more subtle processes affecting living organisms rather than in those produced by violence. All biologists would, he thought, agree that the soma was influenced or modified by its environments. If modifications so produced were capable of so affecting the germ-plasm of the individual in whom the variation arose as to be transmitted to its offspring, then such variations might be perpetuated. He could not accept the proposition that somatogenic characters were not transmitted, and he thought they formed an important factor in the production of hereditary characters. By accepting this theory, a more ready explanation could be obtained how men belonging to a race living in one climate or part of the globe could adapt themselves to a different climate. On the theory of the non-transmissibility of acquired characters, long periods of years would have to elapse before the process of adaptation could be effected. It was known, however, that this was not necessary to produce a race possessing well recognisable physical characteristics. In proof of this, the example of the citizens of the United States was referred to. Sir William Turner concluded by saying that whatever might have been the origin of man's frame, whether by evolution from some animal form or otherwise, it could scarcely be expected ever to attain greater perfection than it at present possessed. Man, however, was also endowed with a spiritual nature, and the kind of evolution which was to be hoped and striven for was the perfecting of this spiritual nature, so that the standard of the whole human race might be elevated and brought into more harmonious relation with that which was holy and divine.

Development of Wisdom-teeth.—A paper on this subject by Dr. R. Levi was read, in the absence of the author, by Dr. J. G. Garson. In January and December, 1885, and in November, 1886, when inspecting the conscripts born in the years 1864, 1865, and 1866, in the military districts of Monza (Lombardy) and Ancona (Marche), he noted the development of the wisdom-teeth. The total number of individuals examined was 732—namely, 366 natives of the military district of Monza (Lombardy), and 366 of the military district of Ancona (Marche). Their average age was twenty years and five months. The two groups were divided as follows in regard to the number of the wisdom-teeth:

Number of the Wisdom-teeth.	Lombards.			Marchigiani.			Total.		
	Number of cases.	Proportion per cent.	Total of wisdom-teeth.	Number of cases.	Proportion per cent.	Total of wisdom-teeth.	Number of cases.	Proportion per cent.	Total of wisdom-teeth.
0	173	47.3	..	155	42.4	..	328	44.8	..
1	43	11.7	43	48	13.1	48	91	12.4	91
2	61	16.7	122	67	18.3	134	128	17.5	256
3	30	8.2	90	22	6.0	66	52	7.1	156
4	59	16.1	236	74	20.2	296	133	18.2	532
Total	366	100.0	491	366	100.0	544	732	100.0	1,035
Average number of wisdom-teeth in each individual.	1.34			1.49			1.41		

The small number of individuals who had an odd number of wisdom-teeth was pointed out. This was evidently a consequence of the fact that the wisdom-teeth appeared generally two by two.

Left-Leggedness.—Dr. W. K. Sibley read a paper in which he argued that man was naturally left-legged. Standing working with the right hand, there was a tendency to balance on the left leg. Race paths were nearly always made for running in circles to the right, and the majority of movements (such as dancing, running, etc.) were more readily performed to the right. In walking, it was natural to bear to the right; crowds as well as individuals did so. Troops started off with the left foot; the left foot was placed in the stirrup or step of the bicycle in mounting; the left foot was the one from which a man took off in jumping. From measurements made by Dr. Garson of the skeletons of the two legs, in 54.3 per cent. the left leg was the longer, and in 35.8 the right. From measurements of 200 pairs of feet, it was found that in 44 per cent. the left, and in 21.5 the right was longer, while in 34.5 they were equal.

THE BRITISH PHARMACEUTICAL CONFERENCE.

The Presidential Address, by C. Umney, F.I.C., F.C.S., etc.

It was at Newcastle, after the meeting of the British Association in 1863, that a few leading pharmacists met with the object of inaugurating an annual Pharmaceutical Conference. At this first meeting the desirability of having at intervals an opportunity of conferring upon matters of interest and importance to pharmacists was shown, and it was thought that a stimulus to intellectual exertion would be given by the prospect of periodical gatherings, and that many who had time and opportunity for research would be induced to contribute papers, while the majority when associated would look forward to an annual gathering as an opportunity of good fellowship.

We are indebted to Schacht for the idea of our annual Conference; to Attfield, Brady, and Reynolds for our excellent organisation; and to the indefatigable secretaries for the success of our annual meetings through a series of years. Reference to the list of members who have been called to the presidential chair reminds me not only of the honour you have done me in electing me to this office, but fills me with misgivings lest I should unworthily occupy the post which has been so ably filled by my predecessors. It is to be regretted that death removed some of our presidents while capable of active work, but gratifying to know that their labours live after them, and that their published researches are ornamental to our "Year-Books of Pharmacy," and of great practical value to medicine and commerce. Presidents Deane, Hanbury, Stoddart, Southall, and Williams took the greatest interest in this Conference, and other presidents who are happily among us to-day, as well as those who are absent, are still in sympathy with this association and its objects. We who have seen the "blue ribbon" that it is customary for the Royal Society to confer on workers in science, given to some of our past presidents, have reason to feel proud of the distinction conferred upon pharmacy through them.

Your late president, when speaking at Bath of the "silver wedding" of the Conference, had a most felicitous topic. I am fortunate in having what should prove an attractive occasion, one indeed which should enlist an enthusiasm equal to that of last year's meeting, arising out of the fact that it was in this very town twenty-six years ago that the British Pharmaceutical Conference had its birth.

"Breathes there a man, with soul so dead,
Who never to himself hath said,
This is my own, my native land!"

The Conference, as you are aware, has met in many important cities and towns in England, Scotland, and Ireland, and on this occasion we are responding to an invitation given twenty-six years ago, when Brady expressed his satisfaction that Newcastle had had the privilege of receiving the first meeting of the Conference, and promised a hearty welcome whenever its members were again disposed to visit his town. Those good friends I see around me to-day evidently had not forgotten the past, and thus it was that at Bath their colleagues said, "that the heart of Newcastle beat with parental affection to the Conference," and, as if to remind us of the geographical position of their town, and to entice our North British friends to come over the border, they said—

"Better loved ye canna be,
Will ye no come back again?"

The subjects upon which my predecessors have addressed you have been most varied. Some presidents reviewed researches in those sciences having a direct bearing upon pharmacy which had been published during their year of office; others spoke to you upon pharmaceutical ethics and politics: some upon revision of the British Pharmacopœia; while others directed your attention to the study of some particular science upon which they spoke as experts. In casting about for a topic upon which I might address you, I came to the conclusion that one of the articles of association of the British Pharmaceutical Conference, agreed to in this town in 1863—viz., "*That one object of the Association should be to maintain uncompromisingly the principle of purity of medicine*," would not be an impropriate theme on which one might say something concerning our every day life that would lead to fresh lines of thought, and such a modelling of our ideas and actions that might tend to make us more accomplished pharmacists and not less successful men of business.

In the days when sophistication was rampant, there were to be found a few at any rate who prized the judicious selection of substances for use in medicine. That the choice was not always used and approved by the physician is shown by the history of the conflicts between physician and apothecary as far back as the reign of Henry VIII., when physicians were empowered to "search, view, and see the apothecaries' wares, drugs, and stuffs," and to destroy such as they found unfit for use. This power eventually passed from the hands of the physicians to the Society of Apothecaries, who separated themselves from the grocers with whom they were by charter incorporated, and against whom they made bitter complaints on account of the frauds that the latter would persist in practising.

To remedy this evil, in the year 1623 the Society of Apothecaries founded an institution for the purpose of making some of the most important preparations for the use of their own members, and although at first operations were on a small scale, being confined to the manufacture of a limited number of preparations, their products were gradually increased both in number and quantity, and eventually we find two centuries later this institution in the foremost rank as producers of medicines of a high standard of purity.

The medicinal compounds in vogue in the seventeenth century were chiefly empirical nostrums or mixtures of substances, some of which neutralized others; and compounding prescriptions and manufacturing medicines was carried on without any reference to scientific principles. While it is true that prior to the organisation of the Society of Apothecaries, two editions of the London Pharmacopœia were published, still the science of chemistry had so little advanced, that it was not until about the time of the tenth edition of the London Pharmacopœia that there was any real knowledge of manufacturing pharmacy.

The signs of the times were not without their lesson to some keen business men in the early part of this century, for it became obvious that traffic in drugs, whether in the condition as imported, powdered, or manufactured into galenicals, might in the future be more successfully carried on by due regard being paid to purity.

There was a new departure, and London wholesale druggists were not handicapped in their start, for their city was the drug market of the world, and the importation and sale of raw drugs had given them great and pecuniary profit. The dissatisfaction of the compounders of medicines no doubt gave rise to this new departure, for the continued complaints of the physician made them aware that for anything other than crude or garbled drugs, but little reliance could be placed in the wholesale druggist, and thus it was, notwithstanding mechanical

appliances were vastly improved for pulverization and other processes, the dispenser had to produce his powders by pestle and mortar if the physician's prescriptions were to be reliably dispensed.

Now in those days it was the practice of the wholesale druggist to send his drugs to a drug miller, who, it is to be regretted, was not so scrupulous of the purity of his products as are the firms who carry on similar businesses to-day, and it is certain, moreover, that the wholesale druggist set a bad example to the miller, for it was not an uncommon practice (as I was once informed by a wholesale druggist who was in business at the end of last century) to send comparatively inert substances to the mill to be ground and mixed with potent drugs.

Early in this century guaranteed powdered drugs were introduced in trade by Thomas Herring, who claimed that his soft, impalpable, bright looking vegetable powders were as pure as the unsightly powders that compounders were then producing for themselves by pestle and mortar. Others followed upon parallel lines with marked success, and the good example of several well-disposed men, striving for excellence, was one of the important steps which have been instrumental in producing the purity, uniformity and perfection so generally to be met with in the powdered drugs of to-day.

Compounded medicines at this period consisted largely of galenicals; and notwithstanding chemical substances were used in medicine, their preparation was imperfectly understood. Chemical science, it is true, had already started on its triumphant march, for Phillips, when reviewing the Pharmacopœia of his time, wrote most ably thirty pages upon the preparations of antimony. Tricks were resorted to in the adulteration of simple chemical substances which leave but little doubt that notwithstanding there was a want of chemical knowledge and manipulative skill, there was no lack of deliberate intention to defraud.

The success attendant upon the production of pure powdered drugs was an incentive to some of our historic houses, and it came about that not only were chemical substances prepared with due regard to their medicinal purity on a larger scale than heretofore, but organic novelties such as quinine, morphia, strychnia, which were now finding uses in medicine, were produced on a manufacturing scale of purity, which, considering the chemical knowledge of the manipulators, was highly creditable. For half a century prior to our first Conference a gradual but steady advance in the direction of purity for medicinal substances was made, and the pharmacists of 1863 did not fail to take cognizance of this; moreover, they saw that the sphere of their labours was being constantly enlarged, and if pharmacy in the future was in any way to be a credit then their work as chemists and pharmacologists must be unceasing.

Since the first Newcastle meeting the rival pharmacopœias of London, Edinburgh and Dublin have been fused into a national pharmacopœia. This has been advantageous in helping forward and maintaining uniformity and purity in medicine. Those of us who have been in harness during the publication and use of three or four pharmacopœias know the effect a well revised edition has upon the commercial standard of crude and manufactured drugs. The British Pharmacopœia, 1885, is an excellent type of what such a book should be, for it adopts a standard that ensures efficiency, and does not attempt to introduce rare and exceptional quality that is only occasionally obtainable to the exclusion of that which is to be had of uniform excellence without difficulty.

There is perhaps no work upon which an expert has to use his judgment with so much tact and skill, so that he may keep both in touch and tune with the medical profession, the pharmacist, the drug merchant and manufacturer, as when he is called upon to edit a national pharmacopœia. He may be misled by statements based on imperfect information, or defective manipulation, and he cannot in all cases obtain facilities for checking the accuracy of published results. The suitable editing of a pharmacopœia becomes apparent when the editor, knowing the requirements of the medical profession and the capabilities of pharmacists and manufacturers, adopts standards and frames "characters and tests" which are acceptable to all concerned, and this without in any degree imperilling that principle which this Association has at heart—viz., to maintain, without compromise, the purity of medicine.

Pharmacists should do all in their power not only when in their own business premises, but also in their public and private capacities, etc., to impress upon the public that household remedies should invariably be purchased of a similar strength and quality to those medicines physicians direct to be used in compounding their prescriptions. If pharmacists would thus aid in educating the public they would rid themselves of much outside competition in which weaker and inferior preparations are sold in lieu of the preparations of a higher standard vended by themselves; and this might be done quite apart from the question as to whether, legally, it is compulsory to retail British Pharmacopœia preparations or not.

Is it not also desirable that pharmacists should cöoperate with the Medical Council in their desire to make the British Pharmacopœia preparations legal for sale, and those of old pharmacopœias obsolete illegal? In my opinion it is most desirable. The Sale of Food and Drugs Act has materially aided in maintaining and advancing purity in medicine. As a rule it is a thankless and almost hopeless task to make communities good by Act of Parliament, and oftentimes the striving of the few will act more beneficially as an incentive to the attainment of a higher standard than any coercion that can be devised. There is a residuum, nevertheless, holding either different or no definite views that prefers not to take action unless under compulsion.

This must have been true in reference to traffic in medicines in the past, or "Drugs" would not have been tacked on to the Sale of Food Act, and our business signalled out as one in which it was necessary that supervision should be exercised for the public good. The working of this Act, in so far as it concerns the drug trade, has not been without friction, due in many cases to the imperfect knowledge of officials, but the novelty now having passed away and the superabundant zeal toned down to a reasonable pitch, only those cases are heard of which indicate fraud on the public. One often wonders when one reads of the number of samples of drugs that have been purchased for chemical examination, most of which seem to turn out satisfactorily, judging from the absence of prosecutions, whether in all districts the analysts are so conversant with the characters and tests commerce of drugs as to enable them to efficiently test substances submitted to them, or to advise the authorities when prosecutions should be unflinchingly carried out, or not instituted.

The highly-trained pharmacist has neither sought nor obtained the post of public analyst in anything like the number of instances he should have done. It may be that, notwithstanding his acquaintance with pharmacy, he lacks chemical and microscopical skill. If this be so, more complete instruction should be given in these subjects, and students should give themselves up to systematic instruction for a period of two or three years at least, otherwise they cannot expect to become competent to fill the post of public analyst. Possibly the clause in the Sale of Food and Drugs Act, which provides that no person shall be appointed as analyst for any place who shall be engaged directly or indirectly in any trade or business connected with the sale of food or drugs in such place, has prevented pharmacists from seeking the appointment, obviously they are at a disadvantage as compared with professional men under this regulation. Surely there cannot be two opinions upon the desirability of impressing the public that the trained pharmacist is not on the same dead level as the traders with whom he is surrounded, and with whom in selling simple commodities he has unfortunately to compete. Could any better indication of the superiority of his training, and a fitness for the confidence of the public be found than his appointment as public analyst?

The public is not slow in taking note, and would not fail to observe that similar appointments were held by medical practitioners, and such observation would in due course necessarily tend to the better recognition of the pharmacist as an educated man, for whose superior knowledge even in trading it would rather pay an extra fee, as compared with the drug grocer who had no information to part with.

It is none the less true now than it was at the commencement of this century, that in order to guarantee one's manufactures there is nothing compared with the simplicity of producing them for oneself.

The regulations with which the Excise have surrounded our manufactures, and which are unequalled in number and stringency in any country in Europe, have been thought necessary in the past in order that the duty upon alcohol may the more easily and accurately be collected. This impost has produced a depressing effect upon the manufacturing pharmacy of this country, which cannot have advanced either the purity of medicine, or our position commercially. For England to have been compelled to purchase in the markets of Germany her alcoholic medicinal preparations, which the exigencies of her trade required should be exported in bond to her colonies and elsewhere, was most humiliating.

We were more to blame than those who continued this part of our fiscal system, inasmuch as we submitted to the yoke for years without complaining or moving in our own interest, and, as a matter of fact, until recently the authorities were not aware that the manufacturer of medicines had any grievance to be redressed.

Happily, within the past year, on account of the broader views prevailing, and the interest taken in our work by the practical men at the head of the Inland Revenue department, there has been an amendment, and the excise regulations which so trammelled us in the past have now to some extent been removed, and at last there is an opportunity of producing most of our alcoholic medicinal preparations, with permission to export them under suitable drawbacks. These concessions will be of commercial value, and the manufacturing pharmacist will have an opportunity in the future of guaranteeing that his products are what they profess to be, and the standard of purity in medicine will thereby be legitimately maintained and advanced.

The Board of Inland Revenue has taken a good work in hand and it must not look back.

England produces chloroform, ether, and other substances from alcohol without opportunity of competing with Germany and other countries, for the Excise take no account of the heavy pecuniary loss entailed in manufacturing such liquids from duty-paid alcohol, and give no rebate either for loss, or for duty, to the manufacturer on exportation.

Why England should be driven to Germany and elsewhere for so many of its alcohol derivatives, of which hydrate of chloral is an excellent type, and why alkaloids, as atropine, veratrine, aconitine, and a legion of other preparations should be imported to the detriment of our trade, and the demoralization of our rising chemists and pharmacists as manufacturers, I cannot conceive.

In my opinion, alcohol free of duty for medicinal purposes, or some facility to work with pure alcohol under supervision, is a most serious and urgent necessity. We are surely all desirous that we may not continue mere purveyors of potent remedies, but that we may be producers also, with a complete knowledge of the products we handle, whether as dispensers or traders. There should be no attempt in the direction of obtaining concessions from the Inland Revenue that are impracticable. The department has recently shown a desire to aid rather than to hamper our manufactures, and there must not now be permitted, even if it should be wished, any lethargy or retrograde movement. Did not Germany for years take tea (valueless for dietetic purposes) out of our bonded warehouses without paying duty, and extract caffeine therefrom, selling it to the world, England included? and has it not been from recent concessions of our Customs authorities that we (thanks to the agitation of a shrewd business man) are now in a position to manufacture caffeine as advantageously as our continental opponents?

The late President of the Chemical Section of the British Association referred at the Bath meeting to the decline of chemistry in this country. While I am not in a position to give an opinion on this subject, as a whole, I fully concur in Professor Tilden's views in so far as the study of chemistry and its application to the manufacture of substances for use in medicine is concerned.

If one seeks the reason why in medicine this has come about, when a generation ago England was quite abreast of other nations in the production of inorganic and even organic medicinal substances, one can only come to the conclusion that something must have militated against advancement. In my opinion two causes at least have been at work—viz., the stringent regulations with which we have been hemmed in by the Excise, and the meagre opportunities of education in research that have, up to a very recent date, been afforded in this country.

Our historic drug houses, who have always acted more or less as manufacturers, have, much to their own detriment, neglected research. Each establishment should have had its chemist engaged in the chemical examination of new remedies for the discovery of active principles, etc., which must have tended to have kept us out of the arms of foreigners for most of our alkaloids and other organic substances now in such increasing demand in medicine.

Manufacturers may state that had men educated for such purposes been forthcoming, they would have gladly embarked capital, with the objects of research and manufacture in view, rather than have remained apathetic; and to some extent this is true. In the future, however, such an excuse ought not to hold good, inasmuch as the Pharmaceutical Society has, at a considerable cost, equipped a research laboratory, which should, before this century closes, produce many men competent to undertake research and manufacture.

There should be no lack of students in the Society's research laboratory. Applications should outnumber vacancies, and men when trained need have but little fear of a demand for their skilled labour.

The Pharmaceutical Society has not unlimited funds, and its moneys cannot all be spent to aid research, but "ways and means" would be no barrier if men were forthcoming.

Let this laboratory be in such demand that there be no vacancies, and the research of such a nature as to be of benefit to medicine and pharmacy, and I have but little doubt that the good friends who honour us by delivering annual addresses to our students, and who hold positions in the House of Commons, our universities, and elsewhere, would co-operate to obtain pecuniary aid in furtherance of our object, and it is not at all likely that our rich city companies, who do so much for education, endow scholarships and vote funds for special researches connected with medicine and surgery, would stand aloof.

One would imagine, if one did not know to the contrary, that we were all agreed upon the desirability of a good scholastic and scientific education, backed by business training for those who practise pharmacy. In my opinion no simpler method can be devised in aiding pharmacists as a body to maintain the excellent principles of this Association, as this thorough training, accompanied by the higher education of some in its ranks in research.

It is quite certain that the pioneers of the British Pharmaceutical Reference had not two opinions on this point, and while it is true that few of the black clouds which threaten us as a trade to-day had gathered in their time, still the path is now, as then, in the direction of education, and I hold that our juniors must have every facility for such a training and thorough education in all those sciences having a direct bearing on pharmacy, as will enable them to take up their proper position with the medical profession and the public. It was not required of the men who met at Newcastle, in 1863, that they should prove their qualification by the possession of the Pharmaceutical Society's diploma. In those days there were no compulsory examinations, as you are aware.

Examinations are not an unmixed blessing, subject as they are to no inconsiderable abuse, and the craze to pass examinations against time has created a state of things which may in the end prove anything but a boon to the pharmaceutical body of the future. It is to be feared that if the students of to-day where asked why they studied, that by far the larger proportion would be bound to acknowledge that they were only occupied in cramming into themselves in the most rapid and easy fashion the minimum amount of information that would help them to pass their examination.

One cannot help regretfully remarking upon this abuse of education, and the failure of the majority to thirst after knowledge for its own sake. When one reminds the average modern student that "knowledge is power," he seems sceptical, and often replies that the information obtained in pharmacy is much too narrow in its scope to lead to reward, and he invariably treats with indifference statements that may be made in reference to the influence that applied chemical and botanical knowledge has upon the world's commerce. He fails to grasp the lessons that are to be found on all sides, and only the thoughtful few are impressed when one gives palpable examples, with the object of proving the marvellous effect science has upon commerce.

The pharmacists of Newcastle can point with sorrow to a vast industry of the Tyne which has been partially dislodged and well nigh ruined, solely a result of applied chemical knowledge. I refer to the manufacture of alkali by the Leblanc method and its present production by the ammonia process. Since the time also when the Conference held its first meeting in this town, and at which period our supplies of cinchona were drawn almost wholly from the South American Continent, what a change has come about.

Who could have thought when botanists and planters experimented in Ceylon, the Nilgiris and Java, that in less than one short generation we, who at one time contemplated a cinchona famine, should now be constantly heard to say, "Hold—enough?" Are not these good illustrations of the working of science? Examples might be multiplied and men named to show that the able pharmacologist can leave footprints that extend not only to medicine, but also to commerce. Did not Daniel Hanbury make an indelible mark? Those who knew this past President of our Association are aware that "Pharmacographia," compiled, as it was, after years of laborious research (looked upon as a labour of love), has been not only a boon and a guide to students of materia medica, but a material help to those who grow, collect, ship or import drugs; few publications have done more to aid than one object of this Association, viz., the maintenance of the purity of medicine, than this work of Hanbury and Flückiger.

I regret my inability to address you upon topics with which you as dispensers of medicine are more immediately concerned; but as several of my predecessors have done this most ably, and as I from the nature of my business am only imperfectly acquainted with this aspect of pharmacy, I trust that this reference will be accepted as an apology for not having followed the beaten track.

I have passed in rapid review a few of the leading features connected with the purity of medicine during this century, and in my divergence to matters connected with or around the subject I have endeavoured to show what has been done spontaneously, and under coercion, and from force of good example, together with the commercial results of applied botanical and chemical knowledge.

Notwithstanding the divergence of the various paths over which pharmacy has been trodden during the last three quarters of a century, most of the roads have finally led to one goal, around which there is one of the fairest portions specially and attractively laid out for the maintenance of the purity of medicine. We who are assembled on this pleasant and reputable spot to-day have gained more speedy access than we should otherwise have done, had not steps on easy paths been thoughtfully hewn for us.

Let us not "rest and be thankful" for the small advance we have made, but rather use our position as a ledge upon which we may firmly plant ourselves, with a determination to advance to heights which, without our present vantage ground, would have been inaccessible, and may we zealously toil to so maintain and advance pharmacy as to be worthy of those who at Newcastle twenty-six years ago founded the British Pharmaceutical Conference.

BRITISH MEDICAL ASSOCIATION.

LEEDS MEETING, AUGUST 13th to 17th, 1889.

(*Continued from page* 567.)

PHARMACOLOGY.

Sir WILLIAM ROBERTS, M D., F.R.S., presided over the Pharmacology and Therapeutics Section, and put before the gathering some practical points in the use of antacid remedies in dyspepsia and gravel. He observed that nothing could be more striking than the contrast between the activity of the present day in regard to these matters and the apathy and stagnation of forty years ago, when he first began the study of medicine. They were evidently entering on a period of important advances in the healing art, and the time seemed not far distant when therapeutics might at least fairly claim a position as one of the exact sciences. Gastric antacids were employed in two distinct classes of cases—in acid dyspepsia, and in a variety of conditions characterised by great irritation of the stomach, often with vomiting, which was sought to be allayed by the administration of milk mixed with lime-water. Sufferers from acid dyspepsia were in the habit of relieving their pains by the use of antacids. Was there any harm in this habitual practice? Did dyspeptics purchase present ease at the cost of some future detriment? He had, naturally, regarded a practice so artificial with considerable misgivings, but the more extended his experience had become the more he had been satisfied that, with due precautions, the practice was harmless, and he knew of no valid evidence from any other quarter to justify a contrary conclusion. By means of a tabular statement he showed the relative antacid potency of the several articles in common use as gastric antacids, and, speaking of renal antacids, said the use of alkalising agents for the prevention of uric acid gravel stood on quite as rational a basis as the use of antacids for the relief of acid dyspepsia. The essential thing in the prophylactic treatment of uric acid gravel was to guard the urine from precipitating within the precincts of the kidneys. The subject was one of great interest, both in regard to its therapeutical issues and its physiological bearings, and he knew of none more likely to yield valuable results to a skilled and patient inquirer.

Dr. D. J. LEECH (Professor of Therapeutics in the Victoria University, Manchester) contributed a paper on "Hypnotics and Analgesics," in which he stated that very many drugs had recently been introduced as hypnotics. Almost all of them were derived from the substances belonging to the methyl and ethyl series. He pointed out that the admission of chloral hydrate was not devoid of danger if large doses were given, since it tended to weaken the heart's action. The chloral habit had probably caused many deaths. After describing the effects of the various fresh hypnotics, and their freedom from danger, even in large doses, Dr. Leech alluded to the possibility which existed of producing new ones which might have even more beneficial effects than those they now knew of. The substitution of one kind of atom for another had a distinct effect on the influence of the compound produced. They now knew that the introduction of one group of molecules tended to produce a sleeping drug. It might be possible to find groups which relieve pain, and in this way a substance as powerful as opium, but without its ill effects, might possibly be built up chemically.—Dr. JOHN GORDON (Aberdeen) described the result of a series of experiments with urethane. He said that he found it a valuable sleep-producing drug in cases of sleeplessness where there was no marked pain. It was highly useful in cases of hysteria, overwork, bronchitis, and pneumonia. He noticed, however, that in some cases it had a tendency to cause irritation of the stomach after prolonged action. When it acted he found that its action was always prompt, that the sleep it produced was pleasant, tranquil, and natural, and that the patient always awoke refreshed after its administration. The following gentlemen took part in the discussion upon the two papers:—Drs. Roberts, C. Charles, Needham (Gloucester), Richards, and Woods.—Papers were afterwards read by Dr. T. C. Charles (London) on "The Hot-air Treatment of Pulmonary Consumption;" by Dr. T. C. Taylor on "Grand Canary, its Climate and Waters;" and by Dr. A. C. Miller on "The Mountain Cure of Phthisis, with special reference to its adoption on Ben Nevis."

Dr. BURNEY YEO (Mayfair) introduced the subject of "Foods for Invalids and Infants," and in the course of an able paper suggested that, in modern times, they were drifting into a tendency to over-feeding in the cases of acute febrile disease, and that they habitually, and in a routine manner, administered too concentrated forms of food, more especially when they considered that fever patients should be given much water. They gave too little water, too little vegetable and too little saline water. Having referred to the relative advantages and disadvantages of milk and beef tea as food in acute diseases, he suggested that both might be occasionally advantageously replaced by other forms of food. With regard to the food of infants, Dr. Yeo called attention (1) to the modern difficulties attending breast-feeding, partly owing to the indisposition manifested largely by women in the present day to suckle their offspring; (2) to the feeding of the wet-nurse with the view of maintaining the healthy condition of the milk secretion; (3) to the assertion that the hand-fed infants prosper better than breast-fed infants; (4) to the substitutes for breast milk.

Dr. SIDNEY MARTIN (London) gave a *résumé* of the proper dietary in health and disease. In the case of disease the same kind of foods were given as in health, but they were varied according to the condition of the digestive organs of the body generally. Fats must be given in a form easily taken up by the body, but in many cases had to be cut out altogether from the diet. Dr. Martin finally directed attention to the importance of mineral foods, both as regards salts and water. Some people drank too little water, and that too irregularly. Regulation of water drinking was often an important point in the treatment of dyspepsia.

In the course of the discussion which followed, the PRESIDENT referred to the existence of what was called the Bread Reform League, by whom they were told that unless they restored the bran and husks to the bread all sorts of evil would arise. They might, however, rest assured that man was on the right track with respect to his diet, for the race was improving. He ridiculed the assertion made that unless they restored the husks and bran to bread there would be dreadful consequences, and pointed out that the properties which bread lacked were found in other foods usually eaten with it.

Papers were afterwards read by Mr. W. McClennan (Glasgow), entitled "Experimental Research on the general comparative action of the natural and artificial salicylic acids to their salts of sodium;" Mr. S. E. Solly (Colorado Springs), on "The Climate of Colorado;" Mr. H. Radcliffe Crocker (London), on "Antharobin and Soziodals in the treatment of skin diseases;" Mr. C. R. Illingworth (Accrington), on "The Therapeutics of the Biniodide of Mercury;" Mr. H. Woods (London), on "The Oxyiodides of Calcium and Bismuth," published in full at page 590; and Mr. T. C. Charles (London), on "(1) some cases of Diabetes, and (2) on Ichthyol."

SOME FRENCH CONGRESSES.

THE CONGRESS ON CRIMINAL ANTHROPOLOGY.

[BY OUR OWN CORRESPONDENT.]

Continued from p. 572.

I ALLUDED in my last communication to the subject of drunkenness, and to the discussion which took place on the prevention of this vice. Drink is the fertile parent of crime. And this leads me on to another Congress which has been held, devoted to the subject of criminal anthropology. Professor Lombroso, of Turin, has devoted considerable attention to this subject, and is the leader of a new school. He is about to publish a book, called "Palimpsests of Prison Life," made up of the writings of prisoners on pottery, rags, ribbons, and on anything but paper. Many important questions were discussed at this conference.

Amongst the questions propounded for discussion was the following: "Do anatomical characteristics exist proper to criminals? and how shall we interpret these characters?" You will see that this is a very important sociological question, and if established, what corollaries may spring from it; for if the convict class are born with the mark of the beast upon them, and if the crimes of violence, theft, murder, follow on the possession of these anatomical characteristics, then the criminal is really a helpless victim to anatomical character—powerless to resist his temptations. He deserves our sympathy. Our laws, in place of being just, are harsh. The criminal, in place of being sent to prison, should be admitted to a hospital for mending morals. To many who are familiar with the description given by Dickens of Bill Sykes, and to others who may have seen in the purlieus of large cities the unfortunates who live there, it may seem a slight problem; and you might feel inclined to say, "Yes, there is a criminal class—you can detect the class, for crime is written on their faces." But I hope to prove this view is superficial, and only takes into account what has been produced on the human face by bad living and disregard of the moral law, by drink, dissipation, and the like. It leaves out what really underlies the problem, which goes back to birth, and has to be put in another form. Are the children born with these characteristics? Have they the criminal stigmata? and if they have the wide orbits, the prominent cheek bones, the distended nostrils, and other signs of degeneracy, must these children grow up as pathological monsters, and in due time, by force of gravity, drift into the army of criminals? I shall probably have to sketch bye-and-bye how Bill Sykes and his class are created, and return to the general question—

viz., the mental and physical differentiation between habitual criminals and persons of good morals and exemplary conduct, and give you the opinions of some eminent men who attended the Congress.

Dr. Lombroso, the famous specialist from Turin, stated in a very learned, elaborate, and temperate report, that there existed a distinct type of criminal man, just as a savage type is still to be met with. From his *post-mortem* examinations of the bodies of criminals, he found that all the subjects presented the same characteristics—wide eye orbits, prominent cheek bones, distended nostrils, and other anatomical appearances, which were also peculiar to savages. Dr. Lombroso went much farther, and to account for cases which could not be explained on the ground of conformity to this criminal type, he fell back upon reversion. This is termed atavism. Thus you may inherit from your grandfather or mother under this view a tendency to pick pockets, etc. M. Lombroso has for years and years been writing on this subject, and is one of the most advanced school, which finds support from many eminent Italian sociological writers.

M. Alvarez Taladriz, Madrid, in a special communication to the Congress, said that the human races were not yet seriously classified. The criminal type was common to all, with ineffaceable and indestructible characters which were not the capricious invention of certain anthropologists. These characters, according to M. Lacassagne, are: Prognathism, hair abundant and crisp, beard absent, skin brown and tanned, oxycephalia, excessive development of the jaws and the cheek bones, obliquity of the eyes, smallness of cranium, receding forehead, large erect ears, muscular weakness—signs which connect the European criminal with pre-historic man or the Mongolian. M. Alvarez Taladriz entered into the wider field of ethnography, and considered nations, concluding that the physiological characters of the criminal type manifested itself in a uniform and constant manner at all epochs and in all races. I cannot in this paper give abstracts of all the speeches made on this side, but many other speakers supported these views, the general conclusions being—putting it into simple English—that "the thief is born, and not made," and that we must admit that we have a variety of the human race produced in accordance with law, who must become criminals. They are suffering from moral insanity, or anæsthesia of the moral senses. As the wolf follows its prey, and kills the sheep, so these human wolves will commit murder; for, in the words of Dr. Watts, "it is their nature to." Their simian ancestry is assigned in some cases as a determining cause for their transgressions.

M. Taverni, professor of the University of Catania, presented a report, made in conjunction with M. Magnan, physician to the Asylum of St. Ann, "On the Infancy of Criminals in its relation with the Natural Predisposition to Crime," in the course of which he said that the task of recognising the genesis of crime in the individual by means of anatomy had not succeeded, and never would succeed. There did not seem to exist a special type of cranium or of brain of criminals any more than of non-criminals. Here I may observe that M. Taverin has touched upon a very important point—viz., as to their being a typical type of skull or of brain, even of the healthy. Kant asked "whether there were two trees in the world which had the same number of leaves," and the answer to the question has been "No." So that, as the typical tree is not an actuality, the typical skull or brain is simply an ideality; and so far as the human casket in which the brain is enshrined is concerned, the typical skull would appear to have a superior claim to any which might be found. The brain of the criminal, though sliced, though stained, and though peered at through the highest powers of the microscope, yet gives no insight into the genesis of crime, any more than did the brain of Napoleon III. as to the genesis of his greatness—the record in both cases being: "The brain and its membranes were perfectly healthy;" so that when we speak of a type, it is something we have ourselves preconceived and built up for our own edification.

Magnan (physician to the Asylum of St. Ann) is well-known as a writer on insanity, etc. He said he did not admit the natural predisposition to crime. He first alluded to the three stages of infant life: (1) The vegetative stage, when the child simply responds to reflex influence, as, for instance, when you give the infant immediately after birth a feeding bottle and tube, it will instinctively suck; or you may excite the same action by putting your finger to the infant's lips. (2) The instinctive stage, when the child is developing senso-motor activity. (3) The intellectual life, when the child is developing ideo-motor activity; all these stages being most important ones. The predisposition to crime does not exist normally, and if the child becomes a criminal, said Dr. Magnan, it becomes so under the influence of passion or of a vicious education. M. Magnan did not deny that there were children born who were degenerate, and whom you saw at once were degenerate, but on the other hand those who were suffering from moral perversion did not always show any perceptible modification of structure so as to be able to brand them during life. The physical stigmata of the criminal, he concluded, are too inconstant to constitute a type.

M. Herbette, who joined in the discussion, uttered a very important maxim when he said "Never let a child think that he is morally condemned because he has characters of evil. You have no right to condemn to a moral death a man, much less a child."

What, after all, does this come to, if we accept the theory that crime is dependent upon organization, that a criminal having a simian or ape-like skull must have the ape's nature, and is not responsible for his actions, and that this criminal class is under the control of the iron law of heredity? It comes very much to what has been summarised by one whom I might call the greatest mind that ever existed—your own Shakspere. In Scene II., Act I., *King Lear*, he puts in the mouth of Edmund the following: "This is the excellent foppery of the world, that when we are sick in fortune (often the surfeit of our own behaviour) we make guilty of our disasters the sun, the moon, and the stars, as if we were the villains by necessity, fools by heavenly compulsion, knaves, thieves, and treacherers by spherical predominance; drunkards, liars, and adulterers, by an enforced obedience of planetary influence, and all that we are evil in by a divine thrusting on." Shakspere was not a scientist in our modern acceptation of the term, so we shall have to go further afield and examine the question by the light of science, and see whether I can give you any arguments that can satisfy scientific minds that criminal anthropology is a pseudo science, and that it owes its existence only to what Benedict called at the Congress—a spirit of dilettantism.

That most charming and observant writer, Dr. Oliver Wendell Holmes, has hit off in his gentle way the fallacies which surrounded what was once a fashionable hobby—phrenology. In the "Professor at the Breakfast Table" he thus defines a pseudo science: "A pseudo science consists of a nomenclature, with a self-adjusting arrangement, by which all positive evidence, or such as favours, its doctrines, is admitted, and all negative evidence, or such as tells against it, is excluded. A pseudo science does not wholly consist necessarily of lies; it may contain many truths, and even valuable ones—the rottenest bank starts with a little specie."

The old phrenological system fell to pieces under analysis, though there was something in it, but not sufficient to warrant the general conclusions that because one had a high forehead he had intellect; that the low forehead denoted villainy; that the great size of the back of the head indicated animal passion. The bumps as a study are now only taken up by the peripatetic professors, who, for a consideration, will tell you your character, and if you wish to know how it is done I would refer you to "The Professor at the Breakfast Table," p. 183, of the small Edinburgh edition. Craniology and craniometry appear to me to rest upon just such a foundation as phrenology. There is a certain amount of truth in it. It is true that certain criminals have bad faces —"villain" is written on every line; this must be credited to the account of the craniologist. Measurement of the skull shows diminution, etc.; this also goes to the credit of the craniometrist. But on pursuing their investigations further it is found that there are criminals who have skulls better shaped than those possessed by many members of the British Association for the Advancement of Science; this goes against the theory. But even though measurement and appearance negative, yet the craniologist has a loophole, because he falls back upon reversion to some ancestral type. I have alluded to the criminal Bill Sykes; his facial characteristics are indisputable, and how is he produced?

We are *too* familiar with the horrors of the Whitechapel murders; but the Whitechapel murders have been the means of directing attention and bringing a fierce light to bear upon the slums and alleys of that vast district included in the East End. The condition of the toilers, and of the non-toilers, in the vast city of London during the last quarter of a century has much improved. Ratcliffe Highway, for instance, and its rookeries, have been swept away, and we owe a very great debt of gratitude to the philanthropists who interested themselves not only in the birds of prey, but in the workers who had to live in such districts as Ratcliffe Highway was. The press, by the publicity which it gave to the condition of the homes, materially helped on in the crusade which of late years has taken place. I need not give descriptions of the fearful surroundings under which young Bill Sykes was brought up, and under which human passions marked on his face the brand of the murderer. With such surroundings as do exist in the present day the surprise to me is not that we have crime and drunkenness, but that we have not more. Virtue is possible and easy when you have no temptations. Bill Sykes is an artificial creation, not of civilization, but of surroundings which are a disgrace to civilization. His type is accentuated by his dress. What a transformation there would be in many of us if we had our hair cut short, and if we were clothed as he is clothed, with hob-nailed boot, with kerchief round the neck, and that coat, and waistcoat, and cap, immortalised by Dickens. Carlyle, in his "Sartor Resartus," tells us that the clothes make the man; with how much truth experience tells us. To clothe a

boy decently and send him to school well dressed is a potent lever to the elevation of that boy. It develops that great factor self-respect; rags and tatters pull down the child, so that clothing plays its part in education of the child of the gutter or the street arab.

If Bill Sykes has children, and they are brought up in the same atmosphere in which he lives, what can we expect but a reproduction? but if the children be taken out of this atmosphere the same transformation will take place, as we see actually does take place when Hodge, the village bumpkin, takes the Queen's shilling and is transformed into the handsome lifeguardsman, who is the admiration of Regent's Park nursery-maids. All are familiar with the admirable delineations of life, drawn by Du Maurier for *Punch*. You have seen Sir Midas a type of wealth; though in evening dress, upon his face there is a stamp of vulgarity, on which, in spite of all his wealth and the accompaniments of it, animal is written. But look, is Sir Midas repeated in his sons? Look at the handsome youths with well-set heads, straight nose, short curled lips, firm chins, deep chests, light flanks, large muscles, small joints and bones, typical types of young England's beauty, and see if you can trace the parentage. They are his sons; but how has the change been produced? They have gone to Eton, Harrow, Marlborough; from thence to Oxford or Cambridge; they have pulled oars in the college boats; they have played cricket, tennis; they have ridden, hunted and shot; they have been brought into contact with much that is best; and if they have not acquired much information, they have attained formation by the process of attrition, just as when you place a number of square stones and shake them in a box for a time, the sharp angles are rubbed off, and the stones come out rounded and polished by the friction. This is what education can do and does do for the sons of Sir Midas, and what is possible for this type is possible for the lower type, if you can bring to bear the proper influences. Amongst the causes which lead to the production of a Bill Sykes type, there is one great factor—drink—and here we are brought into the great problem, the hereditary transmission of the drink crave. The hereditary transmission of drunkenness is indisputable, but as it is controlled and controlable when it appears, we have to look for an explanation, not only in hereditary but in the surroundings of the picture. It is easy to use terms to speak about dipsomania, and the hereditary nature of the drink crave. Look round in whatever circles you may move and endeavour to count the numbers of persons you have known, or heard of, who have died through intemperance, then try to remember or trace what was the fate of their children, girls as well as boys, for, of course, hereditary must affect women as much as men. In the first place, you will not be able to count so many, and then I think you will find that the girls have almost invariably escaped, and that occasionally the sons have gone headlong to ruin. I have paid some attention to this subject, and having attended the deathbeds of many drunkards, and signed the certificates of death, I may give my experience. The children escape in the vast majority of cases, and the girls almost invariably escape. Now why should the girls not suffer? because the education of the girl is different and her temptation less. Habit fixes abstinence in the woman. She is not brought into such close intimate relationship with drink; she has not to go into hotels or public houses to transact her business, and social custom does not press upon her the glass. The devotion of women to intemperate parents and husbands is, to my mind, one of the marvels of creation. I have seen heroism, pure, true, unadulterated self-sacrifice in domestic life in connection with drink that puts into shade the most classic stories.

What habit does for woman other influences conspire to save the young man, so that, though we may all be able to cite cases wherein the drink crave has been transmitted from father to son, yet, there are so many cases wherein that is not the law, that we may take heart and almost repudiate the dogmatism which would fix for that vice an iron law. Now what are the influences at work which counteract and control heredity? I start with the cardinal principle: Man has free will, and this conative faculty is one of the prerogatives of our nature. Dr. Johnson's mode of argument about free will was a very short and decisive one. "Sir," said the doctor, "we know the will is free, and there's an end to the matter." The importance of establishing freedom of the will is apparent. The willing faculty comprises desires and resolves; thus desire is a blind and thoughtless inclination to act; while will is a free and deliberate resolution to act—the faculty of preference enabling us to make a free option in our desires, and the faculty of election to make a free choice in our actions. These states depend upon consciousness, and though there be a series of molecular changes in every act of consciousness, yet there must be something behind besides pure molecular action to account for all the phenomena incidental to the slightest mental action.

Sir William Hamilton tells us that there is something behind or under the phenomena of mind, and one of the most eminent physiologists of the present age in a recent article called "The Force behind Nature" says: "As a physiologist I most fully recognise the fact that the physical force erected by the body of man is not generated *de novo* by his will, but is derived from the oxidation of the constituents of his food. But holding it as equally certain, because the fact is capable of verification by everyone, as often as he choses to make the experiment, that in the performance of every rational movement that physical force is put in action, directed and controlled by the individual personality or Ego. I deem it just as absurd and illogical to affirm that there is no place for a God in nature, originating, directing, and controlling its force by His will, as it would be to assert that there is no place in man's body for his conscious mind." I agree with Dr. Carpenter in the belief that there is a personal Ego underlying the physical basis of life; I admit that the varied phenomena of life, thought of mind, are intimately bound up with the mechanism and physical structure of the body and returning back to the old formula, as a rule, we cannot have the sound mind without the sound body, but I cannot admit it as proved that the doctrine of the correlation of forces can explain mental action, and brain action, or that nerve force may be converted without the internal Ego, into all those high mental endowments which find their highest development in a Milton, a Shakspere, a Newton or a Bacon. And similarly, I cannot but think that man has free will and spontaneity which not only enables him to escape from the thraldom of vice and sin, but to influence the world, and in civilization by the exercise of the power of will, for thus alone the bold expression of Liebnitz becomes possible: "Entrust me with education, and in less than a century I will change the face of Europe." Without free will on the part of the individual the efforts of Society in its reformatory aspect would be simple waste of energy. Ribot, a well known writer on heredity admits that pure mechanism or determinism will not explain the problem unless we add to it spontaneity or free will. Oliver Wendell Holmes says:

"Think not too meanly of thy low estate
Thou hast a choice; to choose is to create."

This power of choosing helps man in what has been called the battle of life, and about which so much discussion has taken place lately in the daily papers. The struggle for existence presses on man and brute, but with a different meaning for man. The law of battle or the law of strife is one for the tiger and the wolf, for the eagle or the hawk; these creatures fulfil their instincts, and endowed with strength and passion, they put forth their endowments for destruction. Their struggle for existence is such that the fittest survive. But man has higher endowments, and the mission of his soul demands something more than the mere struggle for existence, so that the highest law of our being is not only to wage the battle of life skilfully and faithfully, but to wage it so that our reason and conscience may tell us that we have waged it not selfishly or basely. To overcome the tendency to sin which is vice, we have to be armed and fortified; and this is true not only for the class whose condition we have under consideration, but for all of us. In human life passion is always warring, conscience restraining us, and the struggle between our better self and our ignoble self is always going on. It was said of poor Dick Steele that he was always sinning and repenting, and this state is very largely true of the mass of mankind.

What are the influences of forces which, in addition to free will, control heredity? There are two influences at work, which I trust will always be at work, which in the past have done good service—viz., religion and education. By religion I do not mean simple religosity, pure sectarianism, but the spirit which belongs to religion, and the fruits of which are charity, peace, patience, goodness, mildness, continency, chastity, etc. A spirit which is possessed not only by those who believe in a sect, but which is a natural emanation from the human soul; for it is true in all its fulness that vice is as opposed to true science as it is to religion. Here science and religion are at one on common ground. It has often been said, and made a reproach, that medical men are not religious, hence the old saying "*Tibi tres medici ibi duo athei*"—"Where there are three medical men there are two atheists." I question the truth of this saying, old though it is. I find that some of the most scientific men are deeply religious, and recognise its influence and power. There recently died a very eminent member of my profession, a man possessed of the greatest love of science, and who has left upon medicine an imprint. This man, Dr. Wilson Fox, lay dying, but conscious and reconciled, and by him sat holding his hand another eminent man, happily yet alive, Dr. Russell Reynolds. "Reynolds," said Fox, "I see a great light—what is it?" "It is the peace of God," answered Reynolds, and Fox lay back, and in an instant knew what was meant. It is *this* spirit or longing for the peace of God which must pervade humanity, and which must counteract the spirit of the flesh, the fruits of which are uncleanliness, immodesty, luxury, enmities, quarrels, dissensions, drunkenness, murders, all of which come under the catalogue of inherited vices, but which, as I have endeavoured to show,

are dependent on man's own free choice, and can be prevented by certain influence.

The second great force is education, and it hardly requires any argument at the present day to insist upon its power and necessity. It is an obvious truth, that upon education in childhood depends the future of the man. If the education be bad, or conducted under bad influences, we can only expect bad results; but if the education be begun under happy influences, we may expect a bright future; and this education is of two kinds, and is shared in by two—the mother and the teacher. We have seen, as Dr. Magnan pointed out, that one period of the child's life is vegetative, it responds to what we term reflexes, and then comes the dawn of intelligence, when the child responds to higher influences.

It is an old saying, and a very wise saying, and always true in every country, that good mothers make good men. The influence exercised by the woman is as powerful as the influence of the teacher. Both are educating, but the teacher may be only imparting instruction, adding so much knowledge day by day; whilst the moulding process in which character is so much concerned appears to me to attach itself to the home. This is why I commend the modern system of terms, and the long holidays in our upper class schools, as it brings the child into the home, and strengthens and preserves home love. I need not insist very much on the value of education or its power, but a few statistics will at once convince that with the growth of education we have had a corresponding decrease of commitals and crime. The following table was compiled by Mulhall, and gives the annual average of convictions in the United Kingdom, and periods:

The first period:	1840—1849.....	36,039
	1850—1859..	28,898
	1860—1869.....	19,911
	1870—1879.....	16,402

These figures are remarkable, and there is every reason to assign the decrease to the influences of education. With education we have to consider many other contributing factors. If you cultivate a man's intelligence, you awaken instincts which are not dead but dormant. I have spoken on the value of clothes, and their influence on the child. We are now dredging the country and bringing into the educational net children of all classes, and the result must be that we shall lift these children from a state of degradation to a higher level. Besides the instruction in school, which is not simply ABC instruction—order, method, obedience, punctuality, are enforced, whilst the surroundings of the child, the well-lighted and well-ventilated schoolroom, have also educational influences. But the tendency of the times does not stop with education; the State is coming to the aid of the people, the normal condition of the masses is elevated, and the health of the people is better safe-guarded. We have Acts of Parliament to protect the workman, in the mill, and the factory; we have Acts of Parliament to insure that the workman shall live under sanitary conditions; and we have numerous other agencies by means of which the general well-being of the people is secured. But there always comes a residuum which it is difficult to reach; for the lowest class, even, provision is made. We recognise that there are bad fathers and mothers, and fortunately we have recently had an Act passed by which children will be better protected from parental cruelty, and which will enforce parental responsibility. The child has too long suffered. The State is aiding us in other ways in reaching this residuum. For instance, we have industrial schools for the reception of children who have not committed crime, but who are in danger of swelling the criminal class. The good effect of this system of reformatory agency is proved by statistical returns. Since their institution there has been a decline of 51 per cent. in juvenile crime. In 1869 to each million inhabitants there were 458 juvenile offenders; in 1881 it decreased to 215. If we held the theory for an instant that crime was absolutely inherited, and that criminals were manufactured just as we manufacture cotton and wool, as has been said, could we have achieved such results by the combined forces of religion and education. In 1880 there were in the industrial schools of the United Kingdom 28,428 children. We cannot expect that all these children will turn out well, but we have the consolation of knowing that something like 80 to 90 per cent. prove good and useful citizens. There is a difference between an industrial school and a reformatory, though they are frequently confounded. The boy in the industrial school is not a criminal; a reformatory boy has committed some offence, and we had in the reformatories in the United Kingdom, in 1880, 7,135 children, boys and girls.

It is consolatory to know that all this protective work is attended by such beneficial results, as it should stimulate us to further exertion. We may think that we have no responsibility outside our own circles, but whatever position we occupy, we owe a duty to the outcast and the orphan.

To sum up the problem, as presented by the advanced school of thought. The brains of criminals exhibit a deviation from the normal type, and criminals are to be viewed as an anthropological variety of their species. This is the formula. The corollary from this law would be that every criminal should be exonerated from responsibility on the ground that he had a diseased brain. To admit this law would be to admit the existence of a pathological monster, created by nature of bone and muscle, with a special mission for evil, and revenging itself as it were upon humanity by hideous crimes, atrocities, and vices.

I have endeavoured to prove that this theory rests upon a false scientific foundation, that the criminal class is the offspring of civilisation, and that the responsibility for the creation of the criminal rests upon man. The facts I have adduced appear to me to prove incontestibly that vicious character is not necessarily inherited, and that man makes his own destiny, for good or evil.

Medical Miscellanea.

The subject of our next illustration will be G. Anderson Critchett, F.R.C.S.

* * * *

M. C. W. Mansell Moullin, F.R.C.S., has been promoted to full surgeoncy on the staff of the London Hospital, *vice* Mr. John Cowper, F.R.C.S., resigned.

* * * *

It is stated that Father Conradi, one of the colleagues of the late Father Damien in the leper settlement at Malokai, has become affected with leprosy.

* * * *

Dr. Corner, of Manningham, on the occasion of his giving up practice in the town, has been presented by a number of patients and friends with a handsome dish and and a large electro-silver tea tray.

The Sanitary Congress at Worcester.—The tenth annual Congress of the Sanitary Institute commenced at Worcester on Sept. 24th. The proceedings began with a public luncheon, at which Earl Beauchamp, proposing "Success to the Institute," spoke of the value of peripatetic societies which spread abroad useful knowledge among the people, and said if more attention was paid to putting into force existing sanitary laws preventable diseases would be more successfully confronted. Local authorities did not always enforce existing laws with sufficient stringency for the health of the people, and it might be well to attach to the office of coroner the duties of public prosecutor in matters of health. He was certain greater stringency must be observed before the full benefit of scientific discoveries could be reaped.—Mr. Hastings, M.P., replying, said many diseases might be held in check by proper preventive measures, and yet the Registrar-General's returns showed an immense proportion of deaths from causes absolutely preventable. Bad drainage, foul air, bad houses annually caused a number of deaths which was a reproach to the nation. These evils were brought on by want of care and knowledge, often by popular prejudices. Sanitary knowledge was, however, becoming more diffused, and the Institute was doing good work in this respect. A Health Exhibition was afterwards opened.

At the first general meeting in the evening Sir Douglas Galton installed Mr. Hastings as president. Mr. Hastings, in his address, referred to river pollution, and said it would rest with County Councils to say whether they would resolve, armed as they were with great powers, in the exercise of which they would be supported by public opinion, that this pollution should go on no longer. It was useless, however, for the country to purify its rivers unless counties above acted in concert with them. He held that the best method of disposing of sewage was to let it flow in liquid form direct upon the land, where it passed through the natural purified earth and could be returned to an adjacent stream without doing any detriment. He thought the Plumbers' Company was doing great good by training young men to carry out the important work of plumbing efficiently. He dwelt at length on the question of efficient ventilation, the importance of which was not sufficiently recognised, and urged that every municipal and local authority should enforce efficient sanitary by-laws. He also spoke of the sanitary influence of occupation, and urged that every care should be taken to lessen the injurious influences of certain trades.

Hugh Miller, M.D., has been appointed public vaccinator of the district of Birkenhead, *vice* P. M. Braidwood, M.D., resigned.

* * * *

The University of Durham has signalised the meeting of the British Association at Newcastle by conferring the degree of D.C.L. (*hon. causa*) upon Professor Flower, the President, Sir William Turner, and Professor Burdon Saunderson.

An extremely interesting shilling book, called "A Record of Three Years Work," was recently written by the Marchioness of Dufferin, and by reading that in conjunction with the Annual Report of the National Association for supplying female medical aid to the women of India, it is possible to realise the enormous strides made recently in this truly philanthropic enterprise.

* * * *

Dr. Lauder Brunton, F.R.S., has accepted the offer of the Nizain of Hyderabad to proceed to India to repeat the experiments of the Hyderabad Chloroform Commission, and to further investigate the subject. His Highness has placed the sum of £1000 at his disposal. No one could have been chosen more qualified for the task, and we wish him every success in his undertaking.

* * * *

In the report just issued of the Registrar General for Ireland, it is stated that the illegitimate births in the whole of Ireland amount to only 2.9 per cent. of the total births, a ratio greatly lower than that of any other part of the Kingdom, and *á fortiori* much less than that of continental cities, in some of which the illegitimate births equal those of the legitimate. It appears, however, that civilisation and prosperity with the concomitant high standard of education have nothing to do with the exercise of rigid chastity of the Irish women, for we find from the returns that the most incontinent part of Ireland is the well-to-do Province of Ulster. The percentage of illegitimacy in that province is 4.4, against the extraordinary low ratio of 0.7 per cent. which is found in the poverty-stricken Province of Connaught. Indeed, it seems from these returns, that amativeness is a besetting sin of the north of Ireland, for we find also that the highest percentage of marriages under age, both male and female, hail from Ulster.

* * * *

At the present moment there are some two hundred *native* women studying medicine in the medical schools at Bombay, Calcutta, Lahore, Madras, Hyderabad, and Agra, which is the latest one to open a class to the sex. Some will take Indian University degrees, some will come here, or go to the Continental or the American schools, to carry their education as far as possible, though the majority will never proceed further with their studies than to be classified as "hospital assistants." At the outset of the movement it was difficult to find Indian girls sufficiently bold to break through the conventional traditions of centuries, and come forward to adopt the profession; but now there is almost an *embarras du choix*, and rigid supervision is exercised in the selection of those only who are intellectually and physically equal to the training. The National Association now has eleven fully-qualified lady doctors practising in various parts, and of these five were trained in England and six in India. It now only permits ladies to designate themselves "doctors" if their education has been sufficient to permit them to be registered under the Medical Acts in force here, and gives to less highly qualified women the titles of "Female Assistant Surgeon," or "Female Hospital Assistant." It is pleasant testimony to hear that the strictly "Unsectarian" scope of the National Association did not prevent ladies of the various Medical and Zenana Missions from giving it all the help and counsel in their power.

* * * *

Arsenic in Glycerine.—At one of the meetings of the British Pharmaceutical Society, Mr. Louis Siebold read a paper, which produced a considerable amount of discussion, on "Arsenic in Glycerine." He said he had examined a large number of samples of different kinds of glycerine, and found that a considerable number certainly contained arsenic, the quantity of arsenious acid being 1 in 4,000 to 1 in 6,000. The quantity was very large, though some samples were free from arsenic. Mr. Umney, the president, said if arsenic was found in ordinary glycerine, it was a very serious matter. Did it arise from the manufacture or from the bottles? Dr. Allen, public analyist, Sheffield, said the fact in connection with a recent well-known case was very important. Dr. Thrish, Manchester, said he had known cases of arsenic poisoning which could not be traced, but which might have come from patients cough lozenges containing glycerine. Dr. Plowman said they were bound to admit that the quantity was very serious, and they must do everything possible to trace the arsenic, at the same time avoiding a scare. Mr. Siebold, replying, said he carefully distilled the glycerine, which might be pure, but arsenic was undoubtedly present in ordinary glycerine. At the close of the Congress Mr. Reynolds, Leeds, invited the Conference to Leeds next year, and the invitation was accepted.

The Northumberland and Durham Medical Society, with Dr. Murphy as president, hold their first meeting on October 4th. Professor Lawson Tait will deliver an address. The meeting will be held in the Examination Hall of the New Medical College. The meeting will not be limited to members of the Society only; all qualified practitioners will be welcome to attend. After the address the members will hold their Annual Banquet; and this, also, will be open to any qualified practitioners who may desire to be present. It is hoped that this will be one of the largest medical gatherings ever held in the North of England. Let us hope practitioners will do their best to attend.

* * * *

The president of the Health Section, Worcester Meeting, 1889, in his opening address, glanced at a long roll of diseases which depend upon the law of heredity. He maintained that unthriftiness in marriage, which prevailed among the ignorant and degenerate, led too often to intentional neglect of children amounting to culpable homicide. It accounted for the inhuman form of false thrift which, under the name of infant insurance, was spreading its baneful influence even in innocent village communities, and not only tempted to neglect, but too often sealed the doom of hapless infants. Public opinion was not advanced enough to sanction a system enforcing the production of a certificate of health by those about to marry, but he thought the time was at hand to put some check on the appalling waste of infant life which disgraced civilisation, by prohibiting marriage until a man could give reasonable proof that he could maintain his wife, and by prohibiting absolutely marriage under twenty-one. He dwelt on the sickness which might be averted if ordinary medical practice were based on preventive as much as curative lines. He numbered dietetic errors, luxury, overwork, idleness, clothing errors, and intemperance, as preventible causes of sickness and death, and said there would be a constant drag on public health and progress so long as doctors attended people only when ill, and not to conserve the health of the household. He thought a great improvement might be effected if a medical attendant were paid by annual stipend or retaining fee, instead of by visits made.—A paper was read by Dr. Strange, medical officer of health for Worcester, who described the great sanilary improvements effected in that city and their beneficial effects on public health.—Dr. Arlidge read a paper on the sanitary aspects of pottery manufacture.—In the afternoon Earl Beauchamp gave a garden party at Mandresfield Court, and a conversazione took place at night.

We regret to have to record the death of Dr. Henry Harvey Boxwell, of Wexford. This gentleman, who had formerly one of the largest practices in county Wexford, died on Sept. 1st, æt. seventy-nine years. The deceased was a Doctor of Medicine of the University of Glasgow, and a Fellow of the Royal College of Surgeon of Ireland in 1844. He was Physician to the Wexford County Infirmary for the past fifty-two years.

Mr. F. A. Heath, according to the rules, has resigned his position as Honorary Surgeon of the Royal Infirmary, Manchester. Mr. Heath has been connected with the institution for over thirty-three years, he having been appointed House Surgeon in 1853. Mr. F. A. Southam was elected to the vacancy caused by Mr. Heath's resignation.

* * * *

Mr. J. A. Collinson has been presented with a handsome set of brass table ornaments by the nursing staff of the Durham County Hospital, on the expiring of his term of office as house surgeon.

* * * *

The proprietors of the *Nursing Record* are about to publish under the title of "The Nursing Record Series" a number of "Nursing Manuals and Text-books," embracing all the departments of nursing work. The books will be neatly bound, and will be sold at prices easily within the reach of nurses, who we feel sure will appreciate them.

* * * *

Those who suffer from short sight are now sufficiently fortunate in being able to obtain spectacles and eye glasses of superior construction, as compared with those used a quarter of a century ago. Many improvements have been introduced in shape. Amongst the latest addition we have to note the patent of Mr. Bussey. Spectacles made from formulæ are fitted into the handle of an umbrella or walking stick, so that when out walking or inspecting exhibitions the glasses can be brought into immediate use.

* * * *

We regret to have to record a number of deaths after the Pasteur treatment :—

Case IX. (see Provincial Medical Journal, June, p. 362). Gilbert Prosper, æt. eleven years, Bruxelles, bitten severely June 18th. Treated from June 24th to July 9th (*L'Union Médicale*, September 5th, 1889).

Case X.—Jean Baptist, Sotheaux, France, bitten July 5th very severely; treated from 5th to 26th July. Hydrophobia appeared on August 24th (*L'Union Médicale*, Sept. 5th, 1889).

Case XI.—Patrick Waleley, æt. seven years, Newry, Ireland, bitten on May 3rd by a dog which disappeared after biting five other persons. Wound cauterised with nitrate of silver an hour afterwards. Treated at the Institute from the 20th May till 3rd of June. Died June 13th, 1889 (*L'Union Médicale*, Aug. 24th).

Case XII.—Gustave Condurier, æt. seven years, Noyrey, France, bitten on June 9th very severely; wounds washed with phenic water an hour afterwards; treatment commenced from June 15th. Hydrophobia developed on June 24th, an incubation of fifteen days.

* * * *

St. John Ambulance Association. — A public demonstration in connection with the Buxton Centre of the St. John Ambulance Association, was held in the Town Hall, on September 6th, at which there was a large attendance. The gathering was a complete success, and the committee and Dr. Mugliston are to be congratulated upon bringing it to so successful an issue. The men acquitted themselves well in all their exercises, and ably illustrated the great use of "first aid" to the injured, and were loudly applauded for their military precision in the drill. Sir Herbert Perrott then distributed certificates of efficiency obtained by ladies, workmen, and navies. Several ladies also obtained certificates in nursing. A very handsome travelling bag, with stirling silver fittings was presented to Dr. Mugliston, by Sir Herbert Perrott, subscribed for by the members of the Buxton Ambulance classes, as a token of their appreciation of his services as lecturer. Dr. Mugliston, who was taken by surprise at this mark of esteem, expressed his thanks for his pupils recognising in so handsome a manner, any exertion on his part, and trusted that very shortly ambulance brigades would be formed in the outlying districts, so that injured persons should receive immediate assistance, and thus prove the benefits intended by this excellent institution, strongly impressing upon his hearers that "first aid" was in no way to supercede the attendance of a skilled surgeon. The following is a short account, as given in the course of Sir Herbert's speech, of the work done by the St. John Ambulance Association. After detailing the reinstitution of the order of St. John of Jerusalem, the ambulance branch being formed by the Duke of Manchester, about twelve years ago he said the number of certificates granted up to June last were—during the season of 1888-9—"First aid" (males), 14,754; ditto (females), 6,738; nursing (females), 2,725; gross total for past year, 24,217; being an increase on the previous twelve months of 2,036, and of the year before last, 6,499. There were 12,415 medallions issued up to date. Total number of certificates awarded to London Metropolitan Police Officers (exclusive of those granted to the City Police) up to date, 2,231. This number included those presented August 15th, 1889. The Mines Regulation Act, which came into force January 1st, 1888, caused a great increase in the amount of work done. The books presented to Mr. Simpson, hon. sec., were on "physiology," and not "physiognomy," as previously stated. The following gentlemen obtained certificates :—T. A. Croghan, Thomas Woodruff, John Bromley, Joseph Gregory, Joseph Shelmerdine, Sydney Taylor, Percy Taylor, Louis Wall, David Johnstone, M.A., George Howe, Isaac Sutcliffe, George Child, S. S. Brittain, R. B. Lee, George Smith, Robert Todd, William Millen, Martin Kings, John T. Todd, William Day, junr., Robert D. Day, Joseph Day, Walter Broadberry, David Nadin, William Plant, John Bellfield, John Edge, Henry Hampson, George Plant, George Utlay, Samuel Parker, Matthew Wardle, George Grantham, Robert Roberton, Thomas H. Danks, Thomas R. Slack, Bernard Middleditch, Robert D. Parker, Arthur A. Bradley, George Naylor, Jas. B. Wood, John Horsfield, Richard Brinsley (navvies), John Riley, George Fowler, Wm. Hammond, Thos. Wixcey, Henry Thorney, and George Allen. The ladies who secured certificates were as under, those marked with an asterisk also taking certificates for nursing :—Miss Thomas (medallion); certificates, Misses A. Brown, J. Brown, *H. E. Brown, Caswell, E. Caswell, *Mrs. Crossley, *Miss Dale, *Miss Farnworth, Mrs. Haddock, *Mrs. Harrison, Misses *Manlove, *E. Manlove, *B. Manlove, Mrs. Orme, Misses *Parker, Richardson, *B. Sargeant, *V. Sargeant, *H. Sharpe, *A. Slater, *Mrs. Cowley Smith, *Mrs. Stamper, Miss Taylor.

Correspondence, Notes, and Queries.

Communications, Books, etc., should be addressed directly to the Editor, "*The Provincial Medical Journal*," *Horton House, Halifax.*

Matters of business should be addressed to the Publisher, at the Offices, 10, *Friar Lane, Leicester.*

We cannot undertake to return rejected MSS. unless stamps sufficient for their postage are enclosed.

We shall be glad to receive reports of Medical Vacancies, Appointments, Meetings of Societies, etc.

Papers containing passages for consideration should be marked.

Correspondents must please attest their communications with their proper name and address (not necessarily for publication).

Contributions must be written on one side only of the paper.

MSS. intended for publication to be sent in not later than the 16th of the month.

The insertion of any letter in these columns cannot be taken as necessarily indicating our adhesion to the views or statements therein expressed. The same remark applies to articles to which a name or nom-de-plume is attached.

OUT-PATIENT HOSPITAL REFORM AND PROVIDENT DISPENSARIES.

To the Editor of The Provincial Medical Journal.

Sir,—I have tried to lay my views before the profession as to the manner in which the out-patient departments of hospitals and of dispensaries should be reformed. Far be it from me, however to suggest that all those wage-earners who are making *under* 20*s.* per week should be encouraged to seek charitable aid; I would rather follow out the Manchester system, and suggest, as they do there, that the person so situated should be admitted to the provident dispensary at a lower rate of payment than is levied on well-to-do members. All charitable relief should be only temporary, not permanent. As regards the proposed Public Medical Service already referred to, may I ask all who are discussing the resolutions to give their opinion on two other points: (1) whether we should fix a confinement fee, and (2) as to whether we should fix a fee for "home" visits—that is a visit to patients' homes—of course giving doctors the power of refusing to make a "home" visit, else we might not secure so good a class of doctors. If we can arrange a Public Medical Service for those wage-earners who are making up to 45*s.* per week per family, and give them medical, surgical, and dental treatment, and medicines from the chemists, then perhaps it would be better to draw up a scale of fees for confinements and "home"

visits, as has been done for vaccination. This seems to be a growing wish with members of the profession.

Now as regards provident dispensaries, I am aware that a great many doctors object to what is known as the provident system. They do not object so much, I think, to the provident system, as they do to its great abuse. A few who hold hospital appointments object to it because they see in it a reflection of their own actions, and think *one* charity is sufficient. Some who hold club appointments object to it for this reason: when a doctor contracts to treat a club patient he calculates on securing the confinement and vaccination fees, and also those due for the illness of the children. I say nothing of such objections. In fact I had rather not notice such issues, for it is so like the pot calling the kettle black when one hears a doctor who holds a provident dispensary or club appointment lecturing one who is attached to an hospital. Others, again, object because the rules of the provident dispensary have been drawn up with an utter disregard as to whether the proposal rests on a sound financial basis. Remember I am not now speaking of a charity proposal. No tables of the rates of sickness seem to have been consulted; little or no attention seems to have been given to the fact that the extremes of life are admitted on equal terms of payment with adults. In fact, infants are admitted *at a lower* rate of payment, although their average rate of sickness may be put down at fourteen days per annum, while the adult generally averages nine days. Even the industrial classes escaped this unpardonable blunder and grasped the importance of the age limit, for they admit only those between the ages of eighteen and fifty. Suppose the originators of the Medical Sickness Society had not secured the advice of an eminent actuary, is it likely we should have adopted the proposal? Yet evidently the promoters of the provident dispensary scheme never thought of doing this, or if they did they have not acted up to it. Had they done so it would have saved much subsequent trouble. However, this is another proof of what I have said elsewhere of the fatal tendency we medical men have of trying to introduce the element of charitable aid, even when we are dealing with well-to-do wage earners. Again, the originators do not seem to have even fixed a rigid wage limit, and with this result, that the provident dispensary is now as grossly abused as are sick clubs and hospitals. Again, they made a rule which must prove deadly to any insurance scheme, namely, that a person by paying what is known as the "sick entrance fee" had the power to demand *immediate* treatment. Fancy any insurance company giving immediate benefits, and that, too, without a medical certificate! Therefore a great part of the failure of the provident scheme is due to this: that there is little or no use paying while well, as there is no difficulty in joining when sickness comes. Here the very essence of the insurance system is perfectly ignored, as this allows the wage-earner to join when ill, and to leave off paying when well. Take, again, another rule, which says "Not more than four children of one family shall be charged for, all the others being free to benefits." What is the result of this? Dr. Stewart, of Manchester, has shown that fully 13 per cent. of provident dispensary members are treated as *free*, or *charity* cases; this, too, in a provident insurance! But, perhaps, this is what business men call "taking a number at a reduction!" Again, there is no "sliding scale" for ages. All insurance companies have been very careful to take particular note of this, as it would be unreasonable to expect all ages to pay a similar amount. Our provident dispensary promoters evidently professed to take in old men, adults, infants, and chronic invalids. Even persons suffering from acute illness are invited to join.

As regards the remuneration of the medical staff, this is insultingly low. In the *British Medical Journal* of 18th January, 1887, I published statistics of eighty-eight provident dispensaries. I found that the doctors were paid on an average a little over 6*d.* per visit. Dr. Stewart found it 4½*d.* Perhaps a wage earner will say that is amply sufficient. Well, ask this working man if he is not paid from 6*d.* to 10*d.* per hour, and if he does not generally secure double wages if he works after 5.30 p.m. Yet he expects the skilled workman —one who has served an apprenticeship of some fifteen years, and who has expended from 600*l.* to 800*l.* on his education—not only to work at a lower wage than he does, but to go out perhaps on a winter's night, to walk a mile or so and prescribe for a patient, and then to walk home (for I do not think the wage-earners would allow him to take a cab at 5*s.*), and all for the magnificent fee of 4½*d.*, medicines thrown in. Why, even the privy and cesspool cleaners are paid better! This is hardly good enough. Although so many hospital doctors think that as many as like to come to the charities should get free aid, little wonder the working-man follows so brilliant an example. But if the working-man says this payment is sufficient, then offer him 4½*d.* for every time you are called out at night, knocking him up and making him go with you. He will then see the absurdity of his argument. For my part I cannot see why some men, sitting in their snug studies, have drawn up a scheme which gives a doctor 4*d.* for a night visit, and I cannot understand why they try to cram so degrading and so very offensive a proposal down our throats. Rather than pay a night visit for these four coppers to a class of the community who consider themselves *many grades* above charity cases I would go out for nothing, treating them as charity cases, than give them the power of *even pretending* they were paying me for my services. And so I hold that the doctor who goes out for such a fee is prostituting himself, and is degrading his profession. If his wife and children are starving he should make some other start in life, or if he is treating these well-to-do people for this sum so as to starve out a neighbouring practitioner—as some of our hospital "brethren" do—he may be doing a sharp business trick, but I question the morality of his conduct. Yet what are we to do. At seventy-two London hospitals the doctors are paid at the rate of 6½*d.* per patient, *not* per visit. All one can say is: "God help us;" for with our many quotations from scripture, we are as villainous and cut-throat a body of men as ever pretended to be so exalted and philanthropic. It was very fine, no doubt, to listen to the Bishop of Ripon preach as he did, but for my part I still hold my own ideas of those doctors who, under the guise of doing good, secretly take the life's bread from their brother, and so make many a doctor's home hungry and sad. We do not wish to restrain charity, but to guide it.

Scarcely any provident dispensary has troubled itself with drawing up a scale of surgical fees. Perhaps these are included in the 4*d.*! The Shipston-on-Stour is the only one which has tried to grapple with this point. Again, no dental tariff seems to have been drawn up. Perhaps the scale to be suggested for the Public Medical Service will do. Another step in the downward direction is the rule which appoints midwives, thereby granting that they are as good as doctors.

I am, however, a firm believer in the provident system. It is the one suited to the financial condition of wage-earners of limited means. It can and should be placed on a firm financial basis. First, I would say that the provident system *cannot* be self-supporting, whatever theorists may say to the contrary. Why, even the Foresters' Friendly Societies have 13,971 honorary members, and look what they make from fines and lapsed membership. Practical Germany has recognised this plain fact. There they have compulsory insurance against sickness, accident, and old age for the wage-earning classes, and the employer has to pay one-third opposite the two-thirds paid by the *employé* (see paper of mine in the *Foresters' Miscellany*, August, 1886). The rent and taxes of a provident dispensary—coal, gas, printing, stationary, drugs, wages of collector, dispenser, and secretary—should be defrayed out of an honorary subscription list. Some have such a list, but it is not sufficient, for I notice that although eighty-eight dispensaries have an income of 52,252*l.* *from members' payments*, still the medical staff receives only 34,989*l.* The doctors, therefore, lose 17,262*l.* by this unbusiness-like transaction, their money going to pay for the requirements of the members; that is, the fee has to pay, besides the visit, the collector, dispenser, printing, coal, gas, and drugs for the members. Would it not be more manly, and far more honest, to do as friendly societies do, and have a separate charge for management expenses, instead of pretending that the weekly payments *all* go to the doctors? Honesty, *even as a policy*, is better than deceit.

One more point must be noted. If we charge at the rate of 1*s.* per man and wife, 6*d.* for each member of a family (taking four as an average), and allow six bottles of medicine at 2*d.* per bottle, this will put a cost of 42*s.* per annum on each family, or 7*s.* per member per annum, or about 1¾*d.* per week—not too large a sum, when we consider the advantages offered. The amount spent per head of the entire population on alcohol is 1*s.* 4*d.* a week.

I have called attention to a few of the most glaring faults of the present provident system, so as to show the great amount of work required. For my part, I wish that the Council of the British Medical Association would spend 50*l.* in obtaining the opinion of a skilled actuary, so as to find out a true working basis for a provident scheme. The Council have done a good work for science. May we ask them to do a little for the general practitioner? I am certain we have only to approach the Council in a friendly spirit, and present our petition to them. All of them have the interest of the profession at heart; and I am fully persuaded that before another year is out the Council will not only have drawn up a scheme which will, if worked, guide and direct true charity into a proper channel, but will—with the co-operation of the branches of the Association—develop a scheme by which the industrial classes of this country will have the power of providing themselves with a very efficient medical service. One thing we must have—and that is, hospital co-operation. No one can point to a provident dispensary having succeeded when it has had to compete with a neighbouring free hospital. On the other hand, we can point to cases where the provident scheme has been a success when it has been actively helped by the hospitals. But I think those doctors acting on hospital staffs are willing to help. The present condition of affairs is a disgrace

to us all, and the sooner we get rid of it the better. I do not wish to be a prophet of evil, but I have no hesitation in saying that the epitaph of the provident scheme will be, if it does not secure hearty and genuine hospital co-operation, "It died because it had not the good wishes and active support of our brethren on the hospital staffs."

Mr. Ernest Hart, speaking at the Leeds meeting of the British Medical Association, said he hoped the branches would at once call meetings to discuss the resolutions, and also that he would give as much space as possible for a report of the discussion.

It now remains to be seen whether the doctors will shake off their almost proverbial apathy, and tackle this question of hospital and dispensary reform. If they do not care to help themselves, they must not expect to be spoon-fed by the Council. The Council is waiting the reports. We should all feel thankful to Dr. T. Holmes, Sir Spencer Wells, and others, for their dogged perseverance in this provident proposal. Will anyone say that had they secured the hospital co-operation for which they have fought for over twenty years, we should not now have a well-directed service? But what provident scheme could carry on a healthful and vigorous life, when it has to compete against the demoralising and baneful influences of indiscriminate and ill-guided charity?—I am, Sir, yours truly,

Liverpool, September, 1889. ROBERT R. RENTOUL, M.D.

P.S.—With the permission of the editor, I wish to suggest that all readers interested in this question of reform should order a number of reprints of this letter, and circulate them among the daily and weekly lay papers, and send them to hospital subscribers and managers. It is only by organised effort and dogged perseverance we may hope to succeed. Reprints cost only a very small sum.

ACUTE RHEUMATISM AND ENDOCARDITIS.

To the Editor of The Provincial Medical Journal.

Sir,—The very able contribution of Dr. Alexander Harkin to the Provincial Medical Journal in May, 1889, stated his belief, that after a chill, when acute rheumatism was developed, the initial mischief was endocardiac.

Also, that frequently, when no cardiac disturbance could be detected, a blister applied promptly to the region of the heart would cut short the attack of acute rheumatism.

This announcement is so startling that we may be quite sure that the readers of the Provincial Medical Journal will hail with great satisfaction the results of the experience of such of the profession as have availed themselves of Dr. Harkin's example, in the treatment of acute rheumatism, if they will kindly supply them to this journal.

Yours faithfully, H. BUSS, M.D.

September 24th, 1889.

ARSENIC EATING.

To the Editor of The Provincial Medical Journal.

Sir,—Dr. Masterman in his paper on "Arsenic as a Cosmetic" seems to doubt there being such a thing as arsenic eating—*i.e.*, taking arsenic in poisonous doses without producing serious symptoms.

In his course of lectures on Medical Jurisprudence, Sir Douglas Maclagan told us that his son visited Syria some years ago, and became acquainted with two men who were regular arsenic eaters. They had accustomed themselves to taking about five grains of arsenious acid as a dose. They showed no symptoms of poisoning, and on examining the urine arsenic was found in abundance.

I am, Sir, yours faithfully,

CHAS. J. MOUNCEY.

NATIONAL HOME READING UNION.

To the Editor of The Provincial Medical Journal.

Sir,—May I inform your readers that the National Home Reading Union has now opened its office in Surrey House, Victoria Embankment, W.C. Miss Mondy has been appointed secretary of the Young People's Section, and George Howell, Esq., M.P., has been appointed secretary of the Artizans' Section. All communications concerning either of these sections should be addressed to them respectfully at this address. Miss Mondy has also been appointed office secretary. All communications, therefore, concerning the general work of union, as well as concerning the general readers' section, should be addressed to her, or to the honorary secretary. All letters of enquiry should be accompanied by a stamped and addressed envelope.—I am, yours truly,

Surrey House, Victoria Embankment. J. B. PATON.

G. Andrews Critchett

THE

Provincial Medical Journal:

A MONTHLY REVIEW OF MEDICAL SCIENCE, LITERATURE, AND BIOGRAPHY.

VOL. VIII.] NOVEMBER 1, 1889. [No. 95.

Our Portrait Gallery.

G. ANDERSON CRITCHETT, F.R.C.S.E.

ANDERSON CRITCHETT was born in London in 1845, a month or so before his father was appointed assistant surgeon to the London Hospital. He was educated at Harrow, and later at Caius College, Cambridge. Those who remember him as an undergraduate retain the recollection of a genial and versatile companion; an enthusiast at athletics, and an ardent student of English literature. After graduating, he studied for some time in Germany and in Paris. His first public association with ophthalmology dates from 1867, when he attended, as a member, the International Ophthalmic Congress at Paris, under the presidency of Von Graefe.

On his return to England he served a long apprenticeship to his father, and there is no doubt that this lengthened association with one of the first ophthalmic surgeons of the time laid the foundation of Anderson Critchett's future career. He became a Clinical Assistant at Moorfields in 1872, a post he held for seven years. In 1879 he was appointed Ophthalmic Surgeon to the Royal Free Hospital, but resigned the office in 1881. In that year he was elected Ophthalmic Surgeon to St. Mary's Hospital. This post he still holds, together with that of Lecturer on Ophthalmic Surgery at the Medical School.

Anderson Critchett was Vice-President of the Section of Ophthalmology at the Brighton meeting of the British Medical Association, and was President of that Section at the recent meeting at Leeds. His address from the chair in opening the discussion on "The Treatment of Immature Cataract" was lucid, eloquent, and masterly. The list of Mr. Critchett's contributions to the literature of his subject is extensive. Apart from their scientific value, his various monographs, addresses, and brochures are distinguished by a finished literary style which is not common, it must be owned, in the writings of busy medical men.

Probably the most important of these various papers are an article on "The Extraction of Cataract," and a lecture on "Eclecticism in Operations for Cataract," which appeared in the *British Medical Journal* in November, 1883. This lecture, which is a model of polished literary work, deals with the selection of a method in the operation for cataract. The whole subject is treated in a judicial manner, and with a liberal but precise judgment. It is an elaborate and highly finished piece of scientific criticism, and is the work of a man who has the rare faculty of generalisation, and who will not be held or hampered by formulæ, dicta, or "accepted methods."

Mr. Critchett's ability as a debater has been demonstrated by many speeches, and on many occasions, but not the least brilliantly by his defence of the operation for cataract with iridectomy, at the International Ophthalmic Congress, held in Heidelberg in 1888, under the presidency of the late Professor Donders.

Anderson Critchett's repute as an operator has grown with years, and it may in truth be said of him that in the department of practical ophthalmic surgery he has few rivals. His method of operating upon cataract, without a speculum, and with no other assistance than that provided by his own skilful fingers, affords an admirable illustration of finished handicraftsmanship. In the records of the progress of ophthalmic surgery in this country the names of "The Critchetts" will always stand forth as the names of two men who, in addition to keen powers of observation, and an enthusiastic pursuit of their speciality, possessed to a remarkable degree that deftness of hand which—although to some extent the outcome of long and laborious practice—is in a larger degree a rare and natural gift.

Mr. Critchett is well known, moreover, as an able and accomplished speaker, and those who were present at his Introductory Lecture, delivered at St. Mary's Hospital in 1887, will remember an address of singular power and earnestness, delivered with all the effect and *verve* at the command of a ready and cultured speaker.

Original Communications.

MEDICAL EXAMINATIONS AND MEDICAL EDUCATION.[1]

By Phineas S. Abraham, M.A., M.D., B.Sc., F.R.C.S.I.,
LECTURER IN PHYSIOLOGY AND HISTOLOGY.

I am duly conscious of the undeserved honour which my colleagues have conferred upon me in entrusting to me the duty of delivering the opening address at this school. A few years ago nearly every institution in the kingdom connected with medical teaching had its inaugural ceremony during the first week of October, but like many other old customs, this one has been gradually waning, and now comparatively few of the metropolitan medical schools besides our own are opening the session 1889-90 in the time-honoured fashion. From my personal feelings at the present moment I cannot help saying that I sincerely wish that these functions had been quite abolished; but from another point of view—such as I should take up if any other member of the staff were now speaking instead of myself—I must confess that I do approve of such annual gatherings, which bring us all together—teachers, students, and friends.

The speakers on these occasions have been more than once twitted for enunciating well-worn platitudes; for repeating *ad nauseam* the admitted fact that the medical profession is a noble one; for telling their hearers what they all know—that they ought to be "good boys," etc.; and for inflicting upon them generally what have been termed "fruitless harangues." I refuse to believe that the words of wisdom which many of you must have heard from my distinguished predecessors in this honourable office have been altogether thrown away. At any rate, if these addresses were in your opinion all nonsense, you would not, I presume, be so foolish as to come and listen to them again. Yet there are present here to-day second, third, and fourth-year's men, and others even more senior, some of whom perhaps do not consider it an absolute waste of time—although it is possible, of course, that they may have some reason to change their minds within the next few minutes!

But I see before me, also, faces which are not familiar, and to you, gentlemen, new students who are to-day making your entry into the profession, I hope that my remarks will not, at all events, appear too stale.

First of all, on behalf of the staff, I desire most cordially to welcome you within these walls. In choosing the Westminster Hospital as your *alma mater* I believe you have done well. This is a small school, and there will be, at any rate, no fear of your being lost here in a crowd; but coming, as you necessarily will do, into close contact with all your teachers, everyone of you may command more personal assistance from them than would be possible, except for a favoured few, in any of the large schools. When, moreover, your time for bed-side work arrives, you will reap the great advantage which the Westminster Hospital affords of an abundance of clinical material in proportion to the number of its students.

I have had some experience of other schools and hospitals, and I have no hesitation in saying that I know of no institution in which the general "form" of the students is better than it is at the present time at the Westminster. Indeed, as I have heard it remarked, there is an atmosphere of work about the place, which makes it quite uncomfortable for the deliberate idler!

Although I may be allowed to suggest that the teaching may have had something to do with it, it is, I think, in a great measure on account of this high professional *morale* of our school that the Dean has been enabled to present to us to-day such a favourable report of the successes of our students at the examining boards. I have reason to believe that no medical school in London can show better, or probably even so good results.

From a calculation which our excellent secretary, Mr. Green, has been good enough to make, it appears that from July, 1887, to the present date, 426 distinct examinations have been attempted by our men at the various boards, and that the percentage of passes has been no less that 77.23. The figures for the conjoint examinations of the Colleges of Physicians and Surgeons have been particularly satisfactory, showing for the past two sessions very close upon 80 per cent. of successes. Of course some subjects may be more difficult to pass in than others, but I may be pardoned if I allude to the fact that the gentlemen who have done me the honour to attend my courses have well kept up the reputation of the school, with a record of 83 per cent. of passes in physiology. I may mention that there has been no attempt here to prevent the weaker men from presenting themselves at the public examinations, or to allow only those to go in who might be likely to get through.

We all know that the great aim of the average medical student is to pass his examinations and to get qualified as soon as possible. This, of course, is quite natural; and I maintain that it should be the constant endeavour of his teachers to assist him in every way to this end. The young doctor will soon find, however, that there is much beyond the final examination, and that a man who has just passed through his school—although he may have conscientiously mastered his text-books and learnt a great deal practically and theoretically about the cases which he has seen or helped in treating in hospital—is really not very far over the threshold of even existing medical knowledge. Medicine, moreover, is progressive; and the competent practitioner who is to do his patients justice, and to keep abreast of the times in information of disease, must be always exercising afresh his faculties of observation and of judgment, and constantly watching the results of others—always, in short, learning. It is, indeed, an old and true saying that a physician who is worthy of the name must be a student until the end of his career.

Your teachers have to bear these facts in mind; and we must not be content with merely "cramming" you for examinations, but must try to equip you with methods of thought and research, as well as with principles and facts, which will be of value to you in the future.

The power of accurately seeing and interpreting natural phenomena can only be acquired by long training and practice, and the modern medical curriculum is, in some measure, calculated to promote the development of the student's faculties. For instance, apart from their direct bearing on surgery and medicine, what better training in minute observation, and in arriving at conclusions where the data are not always clear, can there be than in the proper practical study of Anatomy and Physiology?

In the excellent address to which many of us here present had the pleasure of listening last year, Mr. Stonham showed how very faulty our medical education still is in many

[1] Introductory Address at the Westminster Hospital Medical School.

respects. In most of his strictures I heartily agree. It cannot be too often insisted upon that it is deplorable to see men aspiring to become members of a profession which should be preëminently scientific, and which should be second in culture to none in the land, who not alone are totally ignorant when they enter the medical school of the elementary laws of nature, but who, in some cases, have received but a very imperfect general education. I think, with Mr. Stonham, that no student who is unable to matriculate at the University of London, or to pass an examination of approximately that standard, should be allowed to enter the profession; and I would go further, and recommend that all students, before commencing their special medical studies, should also be compelled to show a substantial knowledge of the principles, especially of chemistry and physics—the sciences, namely, which ultimately underlie the phenomena of health and disease, of life and death, and upon which many of the important subjects of the curriculum are themselves mainly based. I would, moreover, second my friend in his suggestion that the medical course be extended to at least five years; for while the branches of our technical education have been multiplied, and the range of each one has been enormously extended, the time allotted to their study alone has not been officially increased for many years. It may be objected, of course, that if the conditions were made so much more onerous, the supply of candidates for the profession would be materially diminished. But would this be an unmixed evil?

Attention has been frequently called of late to the fact that there are already too many practitioners of medicine, and it is becoming well known that it is impossible for them all to make a livelihood by their calling. Within the last year certain statistics bearing upon the question have been published by a committee of the General Medical Council. It is thereby shown that while the rate of increase of population in England, during the years 1881-86, has been estimated at 1.4 per cent. per annum, the increase of registered practitioners has been at the rate of 2.42 per cent. It is stated that "the net increase of the profession in England during the quinquennium was no less than 826 beyond what was requisite to keep pace with the population, showing an annual excess above average requirements of more than 150." In some places, especially, the plethora of medical men is very great: thus it appears that in 1886 London contained 1943 registered practitioners over and above its due share. If, however, the fully-fledged doctors are as thick as blackberries, the would-be Æsculapians are still more numerous. The average number of registrations per annum of qualified men in Great Britain and Ireland, for the five years ending December, 1888, was 1382, while the corresponding figure for entering medical students, who registered during the same period, was as much as 1921 per annum, and the cry is, "still they come." I do not adduce these figures to discourage you, but I think they forcibly point to two conclusions: (1) That if competition has been severe in the past, it is certain to be still more so in the near future; and (2) that you will all have the greater need for steady work, and for making the most of your opportunities—from the very start—if you are to succeed in the struggle!

I have jotted down some of the qualities which various authorities have stated to be essential to the success of a medical man. First of all there are the four Hippocratic attributes: learning, sagacity, humanity, and probity; and, among a host of others, enthusiasm, diligence and perseverance, reverence, zeal and industry, self-discipline, punctuality and tact, skill, a power to persuade, intention, attention and intensity, integrity, purity and honesty, faith, character, truthfulness, health, hard study, close and diligent observation, a sober and righteous life, humility, sympathy, tolerance of wrong, independence, a strong sense of duty, chivalry, "a love of the profession," and "a readiness to pay a heavy premium in this world for the prospects of reward in the next." I could enumerate a great many more; but perhaps these are enough, gentlemen, to indicate to you what paragons of excellence you must be!

It is true that we occasionally hear of some individual of imperfect education in his work, who has not demonstrated, to his professional colleagues at least, the possession of very many of the above characteristics, attaining by "push," or with adventitious aid, to the position of a so-called "fashionable physician," and gaining a certain amount of reputation among the uninstructed, who cannot detect the fraud. But such instances are, perhaps, uncommon. Considering, indeed, the gullibility of a large section of the public, as evidenced by its unbounded trust in everything which is sufficiently advertised, it is a matter for surprise that the humbug and the charlatan are not more to the fore.

The fact that quacks, in this country at all events, have to hold their heads low speaks well for the growing enlightenment of public opinion. As may be expected, however, the lower class of journalists will sometimes insert, even in the form of articles in the body of the paper, any nonsense for which they are paid, or which they imagine will increase the circulation of their sheets; and in this manner many ignorant persons who still pin their faith upon all they read in the newspapers are frequently duped for the pecuniary benefit of purveyors of universal nostrums and such like. Occasionally, also, we find more reputable journals—probably, no doubt, in all innocence—lending themselves to the self-assertive masked advertisement of some such shady representative of the profession, as I have just alluded to; but is it not astonishing to see, as I did a year or two ago, one of our leading London illustrated papers furthering the interests of a notorious quack by publishing his portrait, with a laudatory biography, and giving, as it were, the stamp of its authority to his unblushingly-absurd allegations. All this may be beneath out notice; but the fact remains that while many a competent practitioner is struggling to 'make two ends meet,' fees which, legitimately, should go to him, find their way into the pockets of unscrupulous adventurers, who thrive on the public credulity and to the general detriment.

Although we conform to the regulations of, and pay considerable sums of money to, Corporations and Councils, which are supposed to have the interests of the medical profession in their keeping, it is apparently for the most part left, as some recent instances testify, to private individuals to go to the expense and trouble of showing up such impostors.

It is satisfactory, however, and only fair, to say that the great organs of public opinion at the present day, show a due appreciation of the rôle of our profession, and are not sparing in their acknowledgments of what a London morning journal has recently called "the inestimable services rendered to mankind by physicians and surgeons"—whom it describes as "that true Legion of Honour, the members of which, officers and men alike, lead noble lives indeed, dedicated to

the alleviation of suffering, to the prolongation of human existence, and to the improvement of the physical conditions in which that existence has to be passed."

When we are helping the sick, or trying to elucidate a problem which may in some way lead to the advance of medical knowledge, we are not thinking of what people will say; but nevertheless such words as those I have just read are some encouragement in our work!

The 'barber-surgeon' is long since extinct, and the hybrid medical tradesman is (or should be) becoming obsolete; the physician of to-day is no longer a mere prescriber of pills and not simply a 'coprogogue,' nor is the surgeon nothing but a 'lopper of limbs' and only worthy of the name of 'Saw-bones.' Voltaire's often quoted *dictum*—that a medical man was one "who poured drugs of which he knew little into a body of which he knew less"—is, indeed, not quite so true now as it was.

We can look with pride at the enormous and steady improvement in the public health, wherever the modern doctor has had his say; we can point to the fact that London—this seething cauldron of human beings—is the healthiest city in the world (in spite of the profusion of doctors!) as a concrete result of the attention paid to the advice of sanitarians.

I have heard a place described by my friend, the Rev. Dr. Haughton, as being so salubrious that nobody could die there. When the very old inhabitants wanted to throw off the mortal coils of this existence they had to go into the next parish! This, however, is not a general experience. We have, indeed, a huge continent of unknown facts in the causation, prevention, and treatment of disease yet before us for exploration. The points of attack are many, and are obvious; and there are plenty of willing and able hands for the work—now, and when you, gentlemen, will be ready for the fray; but the sinews of war, which are as necessary in this campaign as in any other, may be sometimes wanting. It must be admitted that in recent years the State has more and more recognised its obligations to the public weal, and has done much for the science of health, but a great deal is still left to private effort and to individual generosity. We have had to await the initiation, by H.R.H. the Prince of Wales and his Damien Committee, of a much-needed crusade of investigation against one of the terrible scourges of mankind; and we have had to leave gaps in the full knowledge of one of our chief therapeutic aids until an enlightened Indian prince comes forward and handsomely defrays the cost of its adequate re-examination. May some of our Crœsuses nearer home take a hint from his splendid example!

You must excuse me if I take this opportunity of entering a plea for the more thorough study by students of the subject which it is my privilege to teach in this School. We know that the object of most of you in coming here is not to qualify yourselves to become specialists in physiology; and it is also manifest that the time at your disposal for acquiring a real and practical knowledge of such a subject is very limited. We can, indeed, do little more than set you on the way of learning the principles of this, and of many other branches of the curriculum, or than show you how to profit by what you learn hereafter. I am afraid, however, that physiology is not as popular as it might be with the general run of medical students. [N.B.—I do not refer particularly to the pupils of this School, for as we have seen, from an examinational point of view, at all events, our men have not neglected the subject.] This state of affairs, I believe, is partly because men do not seem to grasp the fact that physiology does not consist merely of tables of constituents, series of functions, divergent theories, etc., to be learnt off by heart, but that it is a young science, the data of which are being arrived at by observation and experiment. If students gave as much time and attention to the *things* which are demonstrated to them in the lecture-room and the laboratory, as they do to the *names* which they labour over to commit to memory from their "cram" books, they would not find the subject so very dry. We must remember that the processes of health and disease are not different in kind; they are the effects of the same chemical and physical laws, manifesting themselves under somewhat different conditions. It may truly be said, indeed, that physiology and pathology are part and parcel of one science; there is no distinct line of demarcation between them. There can be no doubt that our knowledge of pathology can be but little advanced except through knowledge and by the methods of physiology. We may safely predict that it will be to the well-trained physiological mind that many of the unsolved problems of disease will the easier and the more surely yield.

It has been said that students can hardly be expected to pay attention to advice which emanates from comparatively young men, or from any, indeed, but the distinguished seniors and pillars of wisdom of our profession. This may be; but a younger man may have a more vivid recollection than his elders of the difficulties of his student days, and a more practical acquaintance with the conditions of student-life of the present generation. At any rate, I shall venture to offer to you some suggestions founded on my experience.

There is considerable difference of opinion among students and others as to the "value" of attending lectures. It obviously all depends upon two things: (1) the lectures and (2) the way they are attended. I can only say that I myself learnt a great deal from lectures, and some of my old note-books are to this day to me more or less useful compendiums of information. I can remember, moreover, that I used to find them very trusty friends indeed on the eve of my examinations! Let me advise you to take down the gist of what the lecturer says. If he knows his business, he will methodise for you the facts of the subject, will emphasise the more important points, and, depend upon it, materially help you to get the best value from your text-books, and from your cases. The art of taking good notes can of course only be acquired by experience; but one soon falls into the way by a little practice. Always correct them when you go home. Sketch all that you can see (there is no need to finish your pictures to the standard of the Royal Academy); a very rough outline will do. Everyone ought to be able to delineate what he sees in some kind of way, and if he cannot the sooner he begins to learn the better. One remembers more or less permanently what one puts down and sees for one's self far better than what one learns by rote from a book. Use you ears, your eyes, your hands—in fact, all your senses if necessary, and satisfy yourselves in every way, as far as you can, that what you read or are told is correct. As I have hinted before, men depend too much upon learning pages of text-books by heart rather than upon tackling their work in a practical manner.

There is one recommendation that I desire to urge. Many of you will find out when it is too late, and will, pos-

sibly, have reason to deplore the omission, that you have not at an early period of your course taken steps to obtain a university degree. You must have observed, in the medical papers, the never-ending controversies over the coveted, although sometimes empty, title of "Doctor." For various reasons—time, money, etc.—the older universities may be inaccessible to some of you, but under the new regulations there will be nothing but a little extra work to prevent any man of ordinary intelligence from attaining to a London degree. Let me strongly advise those who have not already done so to matriculate as soon as possible.

I have said that I profited much from the lectures of my student days. One of the lecturers to whom I owe a debt of gratitude is the brilliant man of science, the Professor of Anatomy of the University of Cambridge, who is occupying the chair on this occasion. I cannot say before him all I would, and could, of Professor Macalister; nor need I detail to you all that he has done for anatomy—that solid ground of our craft—for most of you here are doubtless acquainted with his work. But I must express the peculiar pleasure which I feel in seeing my respected teacher preside in this room to-day.

I have wearied you enough. For your kind patience in listening to my crude and rambling remarks I thank you sincerely. I have one request to make. I ask you to join me in wishing success to the School of the Westminster Hospital!

ON ECTOPIC GESTATION.[1]

By Lawson Tait, F.R.C.S.

Mr. President and Gentlemen,

There is another side to the simple question which you have laid before the meeting in your introductory remarks, and that is, the difficulty one has in selecting a subject that would do honour to the occasion; because, to my immense surprise and, I may add, to my great gratification, I found I had to inaugurate about one of the handsomest buildings ever devoted to the study of the art of medicine. Going over this building this afternoon with Dr. Oliver, I was astounded at the splendour of your installation. I can only say that if your future career in any way corresponds with your buildings, you have a magnificent future before you. As one of the staff of what I may style a rival school, I cordially wish you every success. If we can in any way contribute towards it, we shall be delighted to do so.

To return, however, to the selection of a subject, this was left to me, and I had a good deal of difficulty in coming to a conclusion as to what I should speak about. One may indulge in general platitudes, giving an address which shows how much more we know than our fathers did, at the same time feeling not quite so sure that we know it quite as accurately as they did. Or, on the other hand, one may pick up a special subject, and appeal in detail to the specific advances made. I thought that the second might be the wiser course to adopt; and when at the Leeds meeting I consulted with Dr. Oliver, he agreed that the subject of ectopic gestation, being one which is peculiarly my own, was one upon which I might say something new, at any rate to those who had not read my pamphlet on the subject, and even to some of those who had read it. I therefore chose this subject, which, although rather a special one, occupying in the practice of each individual man no very large field—for none of us see very large numbers—yet when they do occur, these cases place the practitioner in a position of such enormous responsibility, occurring as they do in the most unexpected ways and times, that no subject perhaps presents so much interest to the general practitioner. Ectopic gestation has, too, this additional claim upon your attention—that although it lies in one of the by-paths of practice, still its mysteries have been unravelled in a remarkably short space of time to a very complete extent, not only in pathology, but also in the method of dealing with it satisfactorily, to the relief of suffering and the saving of human life.

You will note that I use the term ectopic gestation; and I would like to say first of all that this term ought to be used exclusively, instead of the older term, extra-uterine gestation or pregnancy. The reasons for this are several. First of all, there is a special variety of this condition which is not covered by the term, extra-uterine pregnancy; and it is always well, when we alter our nomenclature, to alter it in the direction which gives greater precision and covers more ground. We are in the habit of altering our nomenclature often enough from mere fancy. With each in-coming school of pathology there comes a new system of nomenclature, with the result of confusing those who have just left the schools where the latest doctrines were taught. With cellular pathology there was introduced a nomenclature which was disturbed by the molecular theories which subsequently came to the front, and these in their turn have been displaced by the system of pathology based upon the microscopical investigations of lower forms of life. I doubt very much whether the new nomenclature has added very much to our stock of conclusions, though much to our exact information in certain respects. Still, it has disturbed our nomenclature to an extent which is exceedingly confusing, even to a man of my own years. What it must be to one whose hair is grey, and beginning to get thin on the top, I cannot venture to say. I do not, therefore, propose this change without a sound reason for so doing, because the variety of ectopic gestation known as the interstitial is brought within the scope of our term. Then again, the cornual form of pregnancy was regarded as extra-uterine, which is not the case, and it is undoubtedly ectopic. We have, therefore, two conditions which we bring in under the word ectopic, which are not included in the term extra-uterine gestation. Therefore, I maintain that the one word ought altogether to replace the other for the sake of precision and comprehensiveness.

It is difficult in dealing with a subject like this to see clearly what is the best line to follow. We may take the pathological or the clinical classification—and I am not sure that the clinical line is not the best, because I am dealing with the subject for the purpose of helping those who have no time and no opportunity now of following out the intricate details of pathological research, men who are engaged at the bedside, but to whom it is important to know what they ought to do. I will therefore follow it, although it may lead to a little confusion of order. That disadvantage will be compensated for by the clearness I shall gain in addressing those to whom the subject is new, or to whom this term, extra-uterine pregnancy, simply involves a confused notion of a condition far different from that usually met with at the puerperal bedside.

What, then, is the commonest condition with which we have to deal in the matter of ectopic gestation? It is unquestionably the condition in which the catastrophy is so

[1] An Address delivered before the Northumberland and Durham Medical Society, October 4th, 1889.

terrible, that short of a railway accident nothing can be compared with it. One of your patients is suddenly seized with pain in the abdomen; the pain becomes more and more severe, as the hours advance she presents a strange death-like pallor; she vomits; lies on her back; the pulse disappears; the skin becomes cold and clammy; she is clearly dying, and yet there is no very clear ground upon which you can make your diagnosis, and until you inquire into the history you can make nothing out beyond the pain. So sudden is all this, that most of the men who have seen cases of this kind pass on to the *post-mortem* table or into the grave, without a complete diagnosis having been effected, unless indeed the case has happened to fall into the hands of men who have been unfortunate enough to have seen similar cases before. These are the appearances of a woman who is suffering from rupture of the more common form of ectopic gestation. Your patient dies, if not relieved, probably with the true condition unsuspected. A *post-mortem* examination is made; the abdomen is found full of blood; one Fallopian tube is found with a small swelling, and this is found to be the source of the extravasation into the peritoneal cavity. You will find pints of semi-coagulated blood, and when you search for the source of the hæmorrhage, you find it in a rent in the Fallopian tube, from the effects of which your patient has died; this is what we call a ruptured tubal pregnancy, and concerning the pathology of this the greatest confusion existed until very recently; in fact, I may say, with regard to some of the senior members of the profession, the confusion exists at the present time. In support of this assertion I may refer to the report of a clinical lecture which appeared in the columns of the *Lancet* a few weeks since. The lecturer opened his observations with this remarkable sentence, "That only ignorant audacity could presume to make clear the pathology of extra uterine pregnancy." Now I do not know whether it is ignorant audacity on the one side that can make such a charge, or ignorant audacity on the other for attempting to make clear that which was enveloped in obscurity; but if I can succeed in inducing you to believe that the pathology has been made clear, and the treatment precise and successful, then my mission to you will have been accomplished. Let me say that we had, until quite lately, an inherited belief that stood in the way of our understanding the pathology of these cases completely, or indeed at all. Many years ago experiments were made by Lecoste with the view of ascertaining the precise position in which the ovum and spermatozoa met, and impregnation took place. Unfortunately, Lecoste made his experiments upon lower animals, with a bifid uterus, and this has been the source of all the trouble, because the human uterus is single, and the bifidity of the organ is represented by structures which are not uterus at all—viz., the Fallopian tubes. He found that impregnation took place high up the bifid organ, and thought that this was the Fallopian tube, and not the uterus. This led to the mistake that has existed so long. The position in which impregnation took place was not in the Fallopian tubes at all, but in the uterus. Now, normally, the Fallopian tube is lined by a layer of ciliated epithelium, which was supposed to have for its function the sending the ovum down into the uterus, and it was assumed that this function was fulfilled after the ovum had been impregnated. Now we cannot make experiments upon human beings, as upon the lower animals, but we have an unfortunate habit, in many instances, in making experiments upon the latter, of neglecting a precaution which the physicist and the chemist always adopt—viz., of making sure that the conditions of the experiment are the same. Now the conditions of the experiment, it would be found, on careful examination, not to be alike, and the absence of this ciliated layer of epithelium is the precise condition that was neglected. We know now, as nearly as we can know, from the investigations of pathologists, and from direct observations, which will doubtless be completely elucidated before long, that another function for this ciliated epithelium is to prevent the entrance of the spermatozoa into the Fallopian tubes. So long as there is a layer of intact epithelium, the impregnation does not take place there, but only in the uterus. I will not go into the argument upon this point, for the time at my disposal will not allow of it, but some recent researches by A. W. Johnstone and Bland Sutton make it very clear to me. This is the key-note of the subject, and if once grasped makes it all perfectly clear. When the Fallopian tube has been denuded of its layer of ciliated epithelium, these observations show clearly that its surface becomes exactly like that of the uterus, to which the ovum would normally become attached. If there had been a destruction of the ciliated layer, which is not reproduced, then we have the possibility, in the first place, of a spermatozoa entering the tube; and still more important, pathologically and clinically, after impregnation, the ovum may become attached to the walls of the tube, as normally it is to the walls of the uterus. These points granted, the whole thing becomes clear, in spite of the cries of "ignorant audacity" on the subject.

Let us suppose then that this view of the pathology is correct, and everything is clear. Without it everything is as dark as before, but clinical facts and the revelations of the *post-mortem* room fit in so admirably with this assumption, that it is absolutely impossible now to imagine that this hypothesis upon which we are working is anything but perfectly exact.

We will assume then that this later physiology is an improvement upon the older view, that impregnation takes place in the cavity of the tube, and that the attachment of the ovum takes place upon the wall, in consequence of the loss of the ciliated epithelium. Here, however, let me diverge into the clinical aspect of the cases for a moment, and tell you what the history of these cases nearly always is. You will find that the great majority of the cases occur in women who either have never been pregnant, though married for years, or, who have had two or three children followed by an interval of sterility of some years' duration. Now this one clinical fact shows clearly enough that the preventing mechanism was out of gear; that there was something wrong. The intervention of a period of sterility shows that some accident had happened. Then the examination of the tubes will show distinct evidence of mischief. One authority, Dr. Griffith, of St. Bartholomew's Hospital, told me the other day that he was perfectly satisfied as to the correctness of my conclusions that desquamative salpingitis had been well worked out and proved. In many instances then you have a clear history of tubal disease. I cannot go further into this point, because it would take up too much time, but the history generally shows clearly that damage has been done to the tubes prior to the abnormal gestation. Here then we have proof number one of the accuracy of our views. We will now turn to the progress of each condition. Impregnation has taken place, and the ovum has become

attached to the walls of the tube, and goes on growing. We have now to speak of the conditions based upon divisions of the tube, which are largely artificial, but artificial though they be, they have many conveniences to recommend them. You are all of you familiar with the appearances and anatomy of the Fallopian tubes. You know that there is a small part of the tube which is buried in the uterine substance. Then there is another part of the tube which is perfectly free, except that it is kept in place by a meso-salpinx, which is a duplicature of the peritoneum running up one side and down the other, thus enveloping the tube, but allowing of perfect freedom of movement. Now this duplicature of the peritoneum is one of the most important structures in the whole female body. For the purposes of the present discussion, therefore, I ask you to bear it well in mind. Then we come to the division which is known as the infundibulum. This is supposed at intervals, more or less periodical, to be applied to the ovary for the purpose of receiving the ovum ready to pass into the uterus. Whether this view is correct or not remains to be proved, but it is in any case a very interesting subject. At one time, I myself believed that this did take place, but I am now disposed to regard the statement as a myth. It matters little, however, for our purpose whether it takes place or not.

Another point to be discussed is the view that impregnation sometimes takes place in the ovary; that the spermatozoa travel up the Fallopian tube, and spread themselves out over the ovary, and infect the ovum at the moment of its escape. That can be seen readily enough in some of the lower animals who are not provided with Fallopian tubes, and the error arose from the application of these observations to the human female. Now this question, largely asserted upon one and the other side, rests upon the point, Does ovarian pregnancy ever occur? Is there such a variety of ectopic gestation as ovarian? Well, I have examined personally all the specimens to which I have been able to get access, and I have investigated every such case that has ever been put upon record. All I can affirm is that so far no such occurrence has been proved to have taken place. The proof which we demand for an occurrence of this kind is; that a cavity be found in the structure of the ovary; that the walls of the cyst consist largely, if not solely, of ovarian tissue, as demonstrated by the microscope; and that the contents of the cyst consist largely of fœtal structure; or if not fœtal structure, then placenta; and if neither of these three conditions can be substantiated, the case must be put aside, and disregarded as evidence in proof thereof.

I do not mean to say that the thing is impossible, but I mean to say that so far it has not been satisfactorily established. Some of the cases published as such are based on ludicrously erroneous evidence. Not long ago, in the *Transactions* of the Gynæcological Society of America, a case was put on record as a case of ovarian pregnancy. Great care is therefore required in admitting such cases as evidence. It does not matter for clinical purposes whether it is proved or not; if so, the subject is all the more interesting, but I do not suppose it would differ in its clinical relations from a tubal pregnancy. The patient would be exposed to the same dangers, and it would have to be dealt with in the same way.

As regards tubal pregnancy, there is an ample supply of specimens which prove occurrence of all the three forms in the infundibulum, in the middle part of the tube, and in the interstitial part. Now, I may dismiss the interstitial variety with a few words. First of all, it is the rarest; for although I have perhaps the largest experience of any one man of this curious displacement, I have only seen one such case, and I know of only six mounted specimens in this country in which this lesion indubitably exists. It is rare, it is inevitably fatal, for we get no notice as to when rupture is going to take place, and the patient dies before anything can be done. The period at which rupture takes place—that is, when the tube gives way—may be deferred as late as the sixth month, and seldom occurring before the fourth. The tissues are then so vascular that it is only a matter of a few minutes before the patient dies. Alluding particularly to my own case, I fail to see how any human power could have saved her, even if we had been there at the time. The condition is simple enough; an attachment has taken place of the ovum to the tube within the structure of the uterus. There it remains, and expands nearly always in an upward direction, and the rupture takes place on the fundus of the uterus. The rupture is extensive, usually four or five inches in length, and the hæmorrhage is consequently terrific. Nothing could save her but hysterectomy, and by the time the diagnosis is made, all chance of an operation so grave as hysterectomy proving successful would be gone. All the specimens I have seen are identical in character, and it is very fortunate that a variety in which we can do so little, and in which the consequences are so terrible, should be so rare.

We may then pass on to the consideration of the other two varieties. I will dismiss the infundibuliform variety by saying that it, too, is extremely rare. I only know of two well authenticated cases—I will not say on record, for such cases are generally recorded by gentlemen who have too little experience of the method to be followed in establishing these cases, and of the points to be demonstrated. Therefore, when we see figures, except by skilled anatomists or experts in pathology, we have to discount the statements concerning them. For instance, Dr. Granville is quoted as having proved ovarian pregnancy up to the hilt by Dr. Campbell, who actually quotes his pamphlet and plate as quite satisfactory. Now, Dr. Granville's book is very rare, and it took me four or five years to find a copy. When I did so I found the description absolutely incorrect. There was nothing in the plate at all to represent either placental or fœtal tissue, and the text was as follows: "That Dr. Granville was assured by Sir James Clark that thirty years before he had seen a fœtus hanging free in the cavity." I have seen the specimen but can make nothing of it. Where the specimen is in a museum properly put up, you can go back a century, as is the case with the specimens so admirably put up and described by Hunter. Therefore I say that there are only three such examples. It would matter very little, however, if there were more; it would only be a pathological curiosity. Its bearings are precisely the same as the variety now to be spoken of—viz., pregnancy in the middle part of the tube. Let me now remind you of the structure of the Fallopian tube, for this is a fact of the greatest importance. Inside there is the lining of mucous membrane covered with ciliated epithelium, and outside is the peritoneal investment; between the two are clearly defined layers of muscular fibres, longitudinal and circular. The mucous surface is of importance, because its denudation, according to our belief, is the primary cause of the misplacement. The muscular coat has probably some peristaltic action in assisting the ovum and fluids down the tube.

This movement is often seen in operating upon the uterus for myoma, when the vertiform movement follows the removal of the uterus. Of all the layers, however, the peritoneal layer is of the greatest importance, because it is according to the way in which the peritoneal layer behaves, or rather how it is treated, that the ultimate issue depends. Let me call your attention to this diagram; the two folds on the top are supposed to represent the meso-salpinx, which run off from the the flexure of the tube. The ovum, to start again from the point of its growth, goes on developing, and though it is true that the Fallopian tube is capable of a certain amount of distension, this is sharply limited provided the walls are not damaged. The tube is probably capable of the same amount of distension as the gall-bladder or the urinary bladder.

DIAGRAM OF THE TWO VARIETIES OF TUBAL RUPTURE.

1. Into the broad ligament.
2. Into the peritoneum.

a. Blood clot from rupture, opposite placenta. b. Muscular wall of tube. c. Broad ligament.

Beaseley narrates a case in which the Fallopian tube was dilated to such an extent as to hold thirty pounds of fluid. I have myself seen thirteen or fourteen ounces of fluid. On the wall of the tube, however, becomes developed an organ which weakens them; I mean the growth of the placenta. The formation of large venous sinuses on the site of implantation of the placenta diminishes the ability of the tube to distend, and it tears. This coincides with the formation of the 'cake' of the placenta. Up to a certain point the placenta is diffused as a villous layer, but at about the eighth week it becomes restricted to one spot, and this goes on until you get what is called the placental cake. I do not know that the development of this placental cake has an all powerful influence in determining the rupture, but it certainly exercises some influence. The rupture always takes place before the time of the limit of the formation of this placental cake, and the time of the rupture is therefore clearly limited to the twelfth week; I have never met with one later than that. Now the rupture may take place in one of two directions, as indicated in the diagram. In one case the placental cake may have formed upon the site where the layers of peritoneum, having gone round the flexure of the tube, meet; or it may form, on the other hand, upon some part of the wall which is closely surrounded by peritoneum. In the first instance the rupture takes place into the broad ligament; in the latter, into the peritoneal cavity. Although I have been preaching on this subject for twelve years, I have failed to get my professional brethren to see what an enormous difference this makes to the subsequent progress of the case. It means that if this hæmorrhage takes place into the peritoneal cavity it is uncontrolled. If you put a bleeding surface under water you remove one of nature's great hæmostatics—viz., coagulation. If you have bleeding going on into a confined space, which is capable of only limited extension, especially if that space be filled by something that is capable of inducing coagulation, such as irregularly distributed fibres, you have a strong means of arresting hæmorrhage, whereas if the cavity be indefinite in its capacity, there is a corresponding absence of the cause of coagulation. You have here an explanation of the different endings of these cases. In rupture into the peritoneum the bleeding practically goes on unchecked. Everyone knows how if a vessel has not been properly tied, or if a ligature has slipped after ovariotomy, there are no means of checking the hæmorrhage, because the blood does not properly coagulate, and a little vessel from an omental adhesion, which would not be of the slightest consequence in an amputation, would be sufficient to cause death after an ovariotomy. You have thus, in the one case, every possible condition favourable to the continuation of the hæmorrhage; while when the rupture takes place into the cavity of the broad ligament, you have all the conditions favourable to the arrest of the hæmorrhage, hence the latter is rarely fatal. Here then we have a great natural difference between these two varieties of tubal pregnancy: one has no natural tendency to cure, and the other has them all. In the one case you have to do with a patient who will die inevitably unless you interfere, in the other you have a condition which you may safely leave alone. In the one case you have hæmorrhage into the peritoneal cavity, and on the other you have it intra-peritoneal into the broad ligament; and I think I have made it clear that the prognostic importance of the two is as different as it can well be.

Now as to the diagnostic difference between the two. It is very simple, if you think for a moment what the relations of the broad ligament are. Curiously enough, a few weeks ago there was published a case by Dr. Thomas, of Leicester, which is a model of first-rate clinical description, on a case of extra uterine gestation, followed by recovery. He however had not the light that I have endeavoured to shed, or he would better have understood the significance of what he has so well put on record. Within forty-eight hours I had another case, which I might read to show an example of the other class, where death would have resulted in another hour.

You have then to recognise two different varieties, one of intra-peritoneal, and the other of extra-peritoneal hæmorrhage. Now intra-peritoneal hæmorrhage may arise from various causes, such as injury, or from imperfectly checked bleeding after operation. But extending such causes, and speaking from my own experience, and as a gynæcologist, it has only one origin, and that is, rupture of a tubal pregnancy. Mark you, I do not say that there are no other causes, but I have never met with them. To my mind, for all practical purposes, intra-peritoneal hæmatocele and ruptured tubal pregnancy are one and the same thing. And now, what are the symptoms and physical signs? Concerning

intra-peritoneal hæmorrhage I may say hardly anything at all. You palpate gently, and you have obscure fluctuation; very difficult to make out even when the amount of effused blood is large; percussion gives nothing very remarkable; you get dulness here and resonance there, but nothing to indicate categorically what is the precise condition. Vaginally you feel an indistinct boggy swelling in Douglas's pouch, but there is nothing very clear about that either. But the relations of Douglas's pouch are practically unaltered. In the extra-peritoneal variety there may be fifty different causes, such as sudden arrest of menstruation by chill, etc., but I fancy the worst cases I have seen of this kind have been caused by tubal pregnancy ruptured in the broad ligament. Here the signs are positive, and in the first place you have a smooth, tense, rounded tumour in the pelvic region, sometimes reaching almost or quite up to the umbilicus. This is the broad ligament dissected upwards and distended by the blood effused. There is distinct fluctuation. On examination of the pelvis you have a condition which is absolutely distinctive—viz., the whole of the roof of the pelvis is fixed and coming down from each side of the uterus, you have processes of induration extending, just as the ceiling of this room might be were it in wood. You have a more or less flat topped roof, and groins down each side, which indicate the burrowing of the blood along the pelvic fascia. Then there is another condition almost certain to occur if the case be a severe one—viz., stricture of the rectum. I had such a case yesterday. Think for a moment that the broad ligament comes off from the uterus, it gradually opens one fold on either side of the rectum, and if blood dissects it up one of the roads will be on to the front of the rectum and around it, and you have an annular stricture of the rectum, which will not disappear for many months. Now let us go back to the history. First, the history of sterility, then the suspicion of pregnancy. The patient *thinks* she is pregnant. There may be irregular discharges, sometimes profuse menorrhagia, but not often a clear history suggesting pregnancy. But if you have the acute condition, what you want to determine is, is the blood in or outside the peritoneum? and this you can determine on the data on which I have given you. If the symptoms are negative, then the hæmorrhage is *inside* the peritoneum; if otherwise, then outside. I think now you will understand why one gets angry, that men should constantly be telling you that you are urging them to open an extra-uterine hæmatocele. I do nothing of the kind except in one particular case—viz., when the distension of the broad ligament is such that rupture has taken place into the peritoneum. Here the conditions are the same as in intra-peritoneal hæmorrhage. I have never seen such a case, but if I had I should have treated it as if it were a primary rupture of the tube into the peritoneum.

Now let me discuss the conditions of the second variety—the case where rupture has taken place into the cavity of the broad ligament. These are most easily indicated, and easily disposed of. In the act of rupture the ovum is destroyed. The case then resolves itself into a simple broad ligament hæmatocele, which is to be left alone. It will be absorbed, only the convalescence will be prolonged. I advise you to leave these cases alone. Many of my brethren have bitterly regretted having tapped them, because if you lessen the pressure you take away the hæmostatic effect of the pressure, and the cyst will refill, and the woman will as surely die from loss of blood as if the hæmorrhage had taken place into the peritoneum. The cases that go wrong are those that are injudiciously interfered with. If the blood is absorbed, there is an end of the trouble. Sometimes, perhaps in one in ten of the cases, the ovum is not filled, the hæmorrhage being smaller. Then it goes on developing into a series of conditions which I will briefly run over. It may go on into the fourth or fifth month, and then die. This is a very common ending of the broad ligament pregnancy. When it dies it still should be absorbed, or it may suppurate, and then you get those extraordinary cases of abscess bursting into the bladder or rectum, or at the umbilicus, with the discharge of fœtal bones at about the fourth or fifth month. These cases prove clearly enough where the fœtus has been; because if you look at your anatomy you will see that the places from which the discharge will take place are those of election in cases of abscess in the broad ligament from any cause. Its cavity is in immediate relation to the anterior wall of the rectum, and therefore the history of these cases is full of instances of discharge of the fœtal bones *per rectum*—less commonly into the bladder. Then, again, the fœtus may not die, but may go on to full time, distending the peritoneum; and it is extraordinary to what extent this can be carried on. Here is a diagram taken from a frozen specimen, in which the whole peritoneum is lifted off the anterior wall of the uterus, and rises up here, and is lifted off the posterior wall of the bladder, and then left, coming down half way between the umbilicus and the pubes.

After all there is nothing wonderful about that when we reflect what takes place with the pregnant uterus. The whole of the fœtus in such cases is thus extra-uterine. There is nothing inside the peritoneum, proving that the view I took many years ago was the correct one—viz., that these full-time pregnancies were extra-peritoneal. This looks absurd, but Dr. Berry Hart's specimen proves it completely. One of his actual sections is before you in order that you may have visible testimony of the accuracy of the views I initiated. Now, what must be done if it goes on to full time? The only course open to you is to operate and remove a living child. The older treatment was to give doses of morphia, or use electricity, to kill the child. But it must occur to all of you that when they are killed by nature they are not pleasant things to deal with after all. When suppuration takes place in the dead ovary it may go on for years. Considering that we have now made five successful removals out of seven operations I think that the moral question of procuring the death of the child is very serious. I do not pretend to be better morally than my fellows, but I would not go out of my way to kill a child which had every right and every chance of living if we will only interfere. You must remember, too, that these ectopic children are probably the only children these women have. As to the prejudice of their being deformed, I can only say that I have three of them growing up around me, and they are healthy and well-formed in every respect. I have never countenanced the employment of electricity in the treatment of these cases of extra-uterine pregnancy. I would let the electricians and others try their experiments, and when they come forward with better results than mine I will take a back seat. I receive with as much respect as possible the statement as to the value of electricity in the treatment of these cases, but I am content to go on my own way and await the judgment of my fellows. At any rate, it is perfectly certain that if you attempt to kill the fœtus before

the rupture takes place you may have good grounds for what you say. The idea is feasible enough. Given a case of tubal pregnancy before rupture of the tube, kill the fœtus and you may save your patient the risk of a rupture. But there is a hitch, and it is this: I have now seen some ten cases of tubal gestation, and I have never had a chance of examining any but one before the rupture had taken place. The first thing we know of these cases is the patient lying on her back with her legs drawn up, collapsed, and suffering severe agony. Of course, if the electricians can spot these women as they are walking along the street well and good; but if they have to rely on the ordinary methods of diagnosis then their treatment will not have much of a show. Again, if the bleeding is into the peritoneum, of course no needle, electrical or otherwise, will stop that; and if the bleeding is into the broad ligament there is, as I have shown, no need for it. After the seventh month the killing of the fœtus does not relieve your patient from the risks of an operation, *toute au contraire*. The risks of suppuration which are sure to follow are enormous. If, on the other hand, you wait until full time, you can remove a living child.

Now then we come to the most important part. When your patient is dying from the effects of a rupture in tubal pregnancy, what are you to do? The course to pursue was indicated a hundred years ago with the utmost precision, and is now embodied in an aphorism of surgery—viz., in case of hæmorrhage, get at the bleeding point and apply a ligature; the same rule applies here. We know that the source of the hæmorrhage is in one of the vessels of the broad ligament. You open the abdomen and find it full of blood and clots. Do not at first trouble about the blood, but go straight for the broad ligament, or to where a swelling is felt; and if it is not on one broad ligament it will be on the other; then pull it up, put on a ligature, and your patient is saved. In order to sum up what I have to say, let me read the account of the last case in which I operated only a few weeks ago.

On the morning of August 20th, at 1 p.m., Dr. Nelson, of Birmingham, called upon me in reference to a young married woman, æt. twenty-six, whom he had seen that very morning. She complained of a sudden attack of violent pain in the lower part of the abdomen. She rapidly got worse, and when seen by him she was already in a state of collapse. She was acutely anæmic, and presented all the classic symptoms of abdominal hæmorrhage. The one point in the history that gave a clue to the case was that she had gone six weeks over her time without menstruating. He made the diagnosis of ruptured tubal pregnancy, and I had little hesitation in agreeing with him. The patient was brought to the hospital as speedily as possible, and she was found to be absolutely pulseless. I opened the abdomen, and, as one of the spectators afterwards said to me, the rush of blood was as if I had opened a hydrant. Disregarding the blood and clots for the time being, I went straight for the fundus of the uterus, and in a moment discovered that a tubal pregnancy existed, and had ruptured in the right Fallopian tube. I promptly ligatured it, and then proceeded to remove the blood and clots. I then closed the abdomen, leaving in a drainage tube. Not another drop of blood was lost, and the further progress of the case is as follows: At 5 p.m. on same day her temperature was 36°C., and no pulse could be felt, except deep down in the neck. The pupils were widely dilated, and the only sign of life was some slight movement of the diaphragm. The complexion was waxy and sallow. By 11 p.m. the temperature had risen to 38°C., but still no pulse was perceptible at the wrist. It was only thirty-eight hours after the operation that it was possible to count the pulse.

In Dr. Thomas's case the pregnancy ruptured outside the peritoneum, in this it was inside. The trouble in both cases was the same, but in one case the hæmorrhage was limited by the hæmostatic influence of the broad ligament, while in my case there were none of nature's efforts to arrest the hæmorrhage, and in another hour it must infallibly have been fatal. The case was seen and the operation performed in the presence of Dr. Nelson, my assistant (Dr. Teichelmann), Dr. Ostrom, of New York, Dr. Arthur Johnstone, of Danville, Kentucky, and Dr. O'Callaghan, of the city of Carlow, and it constitutes the forty-seventh case of the kind I have operated upon. Why, then, should we let these women die? Surely it is some advance if we can remove from the list of catastrophes of our art at least one such as this, which we claim to have done.

THE MEDICO-ETHICAL TEACHINGS OF OLIVER WENDELL HOLMES.[1]

By A. Emrys-Jones, M.D.,

SURGEON TO THE ROYAL EYE HOSPITAL, MANCHESTER; VICE-PRESIDENT MEDICO-ETHICAL ASSOCIATION

The life and writings of Oliver Wendell Holmes in their literary bearings are so well known, that it is surprising that his medico-ethical teachings which pervade all his writings have been so persistently overlooked. Our profession cannot boast of many who have earned lasting reputations in the literary world, and at the same time have clung with ever-vigilant fidelity to the traditions of all that is best and most progressive in medical life. Holmes is certainly one that we all ought to feel proud of, and we cannot afford to ignore the noble precepts he has given for our guidance. I undertook to fill this literary gap in the hope that it may lead others to undertake the amplification it so well deserves.

It was a puzzle to know how to arrange the subject, and I have preferred, for convenience sake, to adopt the chronological method, and to take his books more or less in the order they were written, and to let him as much as possible speak for himself. This method will perhaps sometimes cause me to resort to repetition which, after this word of explanation, you will understand, and I hope excuse.

Holmes is no longer young, as he was born in 1809, to which year he refers in his chatty reminiscences of his last visit to England as follows: "The year 1809, which introduced me to atmospheric existence, was the birth-year of Gladstone, Tennyson, Lord Houghton, and Darwin. It seems like an honour to have come to the world in such company, but it is more likely to promote humility than vanity in a common mortal to find himself coeval with such illustrious personages."

Holmes took his degree of M.D. at Harvard in 1836, and practised as a physician at Boston 1836-38 and 1840-7. In 1838 he was appointed Professor of Anatomy and Physiology in Dartmouth College, which post, however, he only retained for two years. In 1847 he was appointed to a similar post at the Harvard Medical School, which he held for thirty-five years, and only resigned it in

[1] Paper read before the Manchester Medico-Ethical Association, September 27th, 1889.

1882. At this period we have a delightful glimpse of his life from Mary Russell Mitford, in her "Recollections of a Literary Life." She says: "Dr. Holmes is still a young man, and one of the most eminent physicians in Boston. He excels in singing his own charming songs, and speaks as well as he writes, and after reading even the small specimens of his poetry that my space has enabled me to give, my fair readers will not wonder to hear that he is one of the most popular persons in his native city. He is a small, compact little man (says our mutual friend), the delight and ornament of every society that he enters, buzzing about like a bee, or fluttering like a humming bird, exceedingly difficult to catch unless he be really wanted for some kind act, and then you are sure of him."

This brief biographical sketch is necessary in order to show that by training, natural gifts, and varied experience, Holmes is eminently fitted to discourse on medical ethics. Sure it is also that our profession would be far otherwise than we find it, if more followed the noble example of his life.

Holmes is best known to English readers through the Breakfast Table Series—"The Autocrat," "The Professor" and "The Poet." These were all written when our author was comparatively young. They contain less direct references to medical ethics than some of his latter works, but even in these we notice some very pertinent sayings. In the "Latter Day Warnings," a short poem in "The Autocrat," after dilating on the duties of legislators, haberdashers, preachers, and property dealers, there is a fund of philosophy in the two lines:

"When lawyers take what they would give.
And doctors *give* what they would *take*."

He evidently despairs of the attainment of this high ideal, for he winds up:

"But when you see that blessed day,
Then order your ascension robe."

The medical elements are much more noticeable in "The Professor."

In the opening chapter, referring to drugs, he says: "Here, look at medicine—bigwigs, gold-headed cane, latin prescriptions, recipes a yard long, "curing" patients by drugging as sailors bring a wind by whistling, selling lies at a guinea a piece; a routine, in short, of giving unfortunate sick people a mess of things either too odious to swallow or too acrid to hold, or if that were possible, both at once." He is referring later on to homœopathy in very severe terms. "Not that the wiser part of the profession need him (Hahnemann) to teach them, but the routinists and their employers, the "general practitioners," who live by selling pills and mixtures, and their drug-consuming customers, had to recognise that people could get well—unpoisoned."

The following lines are worth remembering by those of us that are apt to look upon ourselves in our professional capacities as *in* the world but not *of* it.

"You can't keep gas in a bladder, and you can't keep knowledge tight in a profession. Hydrogen will leak out and air will leak in, through india-rubber, and special knowledge will leak out and general knowledge will leak in, though a profession were covered with twenty thicknesses of sheep-skin diplomas. By Jove, sir, till common sense is well mixed with medicine, and common manhood with theology, and common honesty with law, *we the people*, sir, ... will crash down on the lumps of nonsense in all of them, till we have made a powder of them like Aaron's calf."

Referring to the fact that the three learned professions have but recently emerged from a state of *quasi-barbarism*, the Professor says "We must keep the doctors awake by telling them they have not shaken off astrology and the doctrine of signatures, as is shown by the form of their prescriptions, and their use of nitrate of silver, which turns epileptics into ethiopians. . . . . A few score years ago, sick people were made to swallow burned toads and powdered earthworms, and the expressed juice of wood-lice. . . . . *Traces* of barbarism linger even in the greatly improved medical science of our century." Thank thee, O kind professor, for thy over-indulgence to our noble profession expressed in the word "traces!"

In our relation with patients we might well bear in mind the professor's advice to those about making the choice of a physician, viz: "Be sure you get one if possible with a cheerful and serene countenance. A physician is not—at least ought not to be—an executioner; and a sentence of death on his face is as bad as a warrant for execution signed by the governor. As a general rule, no man has a right to tell another by word or look that he is going to die. It may be necessary in extreme cases; but as a rule, it is the last extreme of impertinence which one human being can offer to another."

In a discussion on as to whether the art of healing makes men hard-hearted and indifferent to human suffering, we have a delightful sketch of the ideal doctor in these words: "You may be sure that some men, even among those who have chosen the task of pruning their fellow-creatures, grow more and more thoughtful and truly compassionate in the midst of their cruel experience. They become less nervous, but more sympathetic. They have a truer sensibility for others' pain, the more they study pain and disease in the light of science."

In the Poet, the last of this series, there are some very amusing but highly instructive references to the young doctor, Benjamin Franklin. "The young doctor has a very *small* office and a very *large* sign, with a transparency at night big enough for an oyster-shop. These young doctors are particularly strong on what they call *diagnosis*, an excellent branch of the healing art, full of satisfaction to the curious practitioner, who likes to give the Latin name to one's complaint; not quite so satisfactory to the patient. . . . . Sometimes, in fact, one would a little rather not know the exact name of his complaint, as, if he does, he is pretty sure to look it out in a medical dictionary, and then if he reads *This terrible disease is attended with vast suffering, and is inevitably mortal*, or any such statement, it is apt to affect him unpleasantly."

The description of the doctor's office is racy: "There were ophthalmoscopes, rhinoscopes, otoscopes, laryngoscopes, stethoscopes, thermometers, dynamometers, sphygmographs, pleximeters, and probes and probangs, and all sorts of frightful inquisitive, exploring contrivances; and scales to weigh you in, and tests, balances, pumps, and electro-magnets and magneto-electric machines; in short, apparatus for everything but turn you inside out."

The description of the interview is excellent of the doctor's examining the discoloured spot "with a superhuman air of sagacity, with much corrugation of forehead and fearful concentration of attention!"

After dwelling on this most interesting and rare affection, and asking if there was any objection to showing the case to the Society of Medical Improvement and Medical Observation, hints are given about Morbus Addisonii! So he gave me a recipe, said the Poet, which I took care to

put where it could do no hurt to anybody, and I paid him his fee (which he took with the air of a man in the receipt of a great income) and said "good morning" . . . . Ask landlady to look at it. Said it was a bump, and no mistake. Recommended a piece of brown paper dipped in vinegar . . . . discoloration soon disappeared!

The next interview, after Dr. Benjamin had more experience, was more satisfactory. The Poet had an ugly cut from the carving knife. "It was astonishing to see what a little experience of miscellaneous practice had done for him. He did not ask any more questions about my hereditary predispositions on the paternal and maternal sides. He did not examine me with the stethoscope and the laryngoscope. He only strapped my cut and informed me that it would speedily get well by the "first intention."

Holmes has written three novels, all full of medical interest, namely, "Elsie Venner," "The Guardian Angel," and "Mortal Antipathy." To begin with "Elsie Venner"; this is not the place to describe the plot and purpose of the story; I shall therefore only dwell on the parts particularly referring to our subject-matter. Towards the end of the book we have the following description of Dr. Kettredge:

"The old doctor was a model for visiting practitioners. He always came into the sick-room with a quiet, cheerful look, as if he had a consciousness that he was bringing some relief with him. The way a patient snatches his first look at a doctor's face, to see whether he is doomed, whether he is reprieved, whether he is unconditionally pardoned, has really something terrible about it. It is only to be met by an imperturbable mask of serenity, proof against anything and everything in a patient's aspect. The physician whose face reflects his patient's condition, like a mirror, may do well enough to examine people for a life insurance office, but does not belong to the sick-room. The old doctor did not keep people waiting in dread suspense, while he stayed about talking the case—the patient all the time thinking that he and his friends are discussing some alarming symptom, or formidable operation which he himself is by and by to hear of." This is a hint for young practitioners.

"He came to her (Elsie's) bedside in such a natural, quiet way, that it seemed as if he were only a friend who had dropped in for a moment to say a pleasant word."

There are, I hope, many and an ever-increasing number to whom the following paragraph would apply; at any rate, it contains food for reflection from an ethical point of view:

"Some very silly people thought the old doctor did not believe in medicine, because he gave less than certain half-taught creatures in the smaller neighbouring towns, who took advantage of people's sickness to disgust and disturb them with all manner of ill-smelling and ill-behaving drugs. To tell the truth, he hated to give anything noxious or loathsome to those who were uncomfortable enough already, unless he was very sure it would do them good. . . . . Sometimes, he lost a family of the more boorish sort, because they did not get their money's worth out of him . . . . "

There is much in the life-story of Bernard Langdon from his medical student-days upwards that could be dwelt upon with profit, but we must hurry on and glean some fruits from the next delightful story of "The Guardian Angel."

One of the most important references to this subject is the interview between the old scholars, Byles Gridley, A.M., and young Dr. Hurlbutt, respecting the relationship between the doctor and his young hysterical patient Myrtle Hazard. Dr. Hurlbutt had come to a cup of tea, and afterwards Gridley showed him some old books, and among others, a copy of Fœssius' edition of Hippocrates, and asked the question whether he (the doctor) was conversant with the famous oath, and laid special emphasis as he read:

"My life shall be pure and holy,
"Into whatever house I enter, I will go for the good
"Of the patient: I will abstain from inflicting any
"Voluntary injury, and from leading away any, whether
"Man or woman, bond or free."

And then followed with these words:

"Dr. Fordyce Hurlbutt, are you not in danger of violating the sanctities of your honourable calling, and leading astray a young person committed to your sacred keeping?" Hurlbutt acknowledges that he stands convicted and goes away and leaves the case in his father's care. Myrtle is very violent and frantic at times, but at last calms down, and in referring to this, Holmes utters these weighty words:

"But all this series of mental disturbances left her in a very impressive and excitable condition. This was just the state to invite the spiritual manipulations of one of those theological practitioners who considers that the treatment of all morbid states of mind, short of raving madness, belongs to them and not to the doctors. The same condition was equally favourable for the operations *of any professional experimenter* who would use the flame of religious excitement to light the torch of an earthly passion. So many fingers that begin on the black keys, stray to the white ones before the tune is played out."

There are many short sayings in this volume which plainly indicate how high Holmes' Ethical ideas are; *e.g.*, in reference to Myrtle's case:

"Few households have ripened a growth of womanhood without witnessing some of its *i.e.* (hysteria) manifestation, and its phenomena are largely traded in by scientific pretenders and religious fanatics."

One more extract from Gridley's "Thoughts on the Universe."

"Idols and dogmas in place of character;
"Pills and theories in place of wholesome living."

I shall be content with only one extract from the third novel; in many ways a remarkable book. I refer to "Mortal Antipathy." It refers to the ethics of doctors discussing matters of private interest with their wives. I shall not enlarge as Holmes exactly hits off the danger:

Dr. Butts carried these questions with him. His wife was a sensible, discreet woman, whom he could trust with many professional secrets. He told her of Paolo's revelation, and talked it over with her in the light of his experience and her own; for she had known some curious cases of constitutional likes and aversions.

Mrs. B. buried the information in the grave of her memory where it lay for nearly a week. At the end of that time it emerged in a confidential whisper to her favourite sister-in-law, a perfectly safe person. Twenty-four hours later the story was all over the village. . . . Referring to this later on and speaking of Dr. Butts, it is written:

"He would be a little more careful, he promised himself the next time, at any rate, for he had to concede, in spite of every wish to be charitable in his judgment that it was among the possibilities that the worthy lady had forgotten

the rule that a doctor's *patients* must put their tongues *out*, and a doctor's *wife* must keep her tongue *in*."

Now I come to the last volume—viz., "Medical Essays," from nearly each page of which some words of wisdom might be culled. The well known essay on "The Contagiousness of Puerperal Fever" I would particularly invite every member of the profession to peruse carefully. Holmes brings plenty of proofs for the assertion that medical men have been, and may still be, the means of bringing infection from house to house, especially during the puerperal period, and the eloquent winding up of this essay deserves the highest place not only on account of its deep humanity and pathos, but also its splendid literary style.

"It is as a lesson rather than as a reproach that I call up the memory of these irreparable errors and wrongs. No tongue can tell the heart-breaking calamity they have caused; they have closed the eyes just opened upon a new world of love and happiness; they have bowed the strength of manhood into the dust; they have cast the helplessness of infancy into the stranger's arms, or bequeathed it, with less cruelty, the death of its dying parent. There is no tone deep enough for regret, and no voice loud enough for warning. The woman about to become a mother, or with her new-born infant upon her bosom, should be the object of trembling care and sympathy wherever she bears her tender burden, or stretches her aching limbs. The very outcast of the streets has pity upon her sister in degradation, when the seal of promised maternity is impressed upon her. The remorseless vengeance of the law, brought down upon its victim by a machinery as sure as destiny, is arrested in its fall, at a word which reveals her transient claim for mercy. The solemn prayer of the Liturgy singles out her sorrows from the multiplied trials of life, to plead for her in the hour of peril. God forbid that any member of the profession to which she trusts her life, doubly precious at the eventful period, should hazard it negligently, unadvisedly, or selfishly!"

The next essay, "Currents and Counter Currents in Medical Science," is full of good advice. We learn how professional success should be won "by toil, patience, good sense, pure character, and pleasing manners;" we are shown the dangers of the so-called *practical* man who asks no question of the past or of the future, or of the aim and end to which his special labour is contributing. Such a one we are warned may be building truth into the wall, or hanging humanity on the Cross.

The practice of making profit out of medicines is spoken of in the severest terms, and some of the most scathing diatribes ever uttered against this practice, and against the abuse of drugs, will be found in this essay. It is here that Holmes says . . . . "if every specific were to fail utterly, if the cinchona trees all died out, and the arsenic mines were exhausted, and the sulphur regions were burned up; if every drug from the vegetable, animal, and mineral kingdom were to disappear from the market, a body of enlightened men, organised as a distinct profession, would be required just as much as now, whose province should be to guard against the causes of disease, to eliminate them if possible when still present, to order all the conditions of the patient so as to favour the efforts of the system to right itself, and to give those predictions of the course of disease which only experience can warrant, and which in so many cases relieve the exaggerated fears of sufferers and their friends, or warn them in season of impending danger. Great as the loss would be if certain active remedies could no longer be obtained, it would leave the medical profession the most essential part of its duties, and all and more than all, its present share of honours: for it would be the death-blow of Charlatanism, which depends, for its success, almost entirely on drugs, or at least on a nomenclature that suggests them."

Further on, after excluding opium and a few specifics he says; "I firmly believe that if the whole materia medica, *as now used*, could be sunk to the bottom of the sea, it would be all the better for mankind—and all the worse for the fishes."

Holmes insists all through that less reliance on drugs would result in much more care in ordering all the circumstances surrounding the patients. In his tribute to Professor James Jackson there are clear indications of Holmes' ideal physician. His relations to his patients are thus stated: "His smile was itself better than the potable gold and the dissolved pearls that comforted the præcordia of mediæval monarchs. Did a patient, alarmed without cause, need encouragement, it carried the sunshine of hope into his heart, and put all his whims to flight, as David's harp cleared the haunted chamber of the sullen king. Had the hour come, not for encouragement, but for sympathy, his face, his voice, his manner all showed it, because his heart felt it. So gentle was he, so thoughtful, so calm, so absorbed in the case before him, not to turn round and look for a tribute to his sagacity, not to bolster himself in a favourite theory, but to find out all he could, and to weigh gravely and cautiously all that he found, that to follow him in his morning visit was . . . . a medical education."

"He (Dr. Jackson) would have it that to *cure* a patient was simply to *care* for him. I refer to it as showing what his idea was of the relation of the physician to the patient. It was indeed to care for him, as if his life were bound up in him, to watch his incomings and outgoings, to stand guard at every avenue where disease might enter, to leave nothing to chance, not merely to throw a few pills and powders into one pan of the scales of Fate, while Death, the skeleton, was seated in the other, but to lean with his whole weight on the side of life, and shift the balance in its favour if it lay in human power to do it."

Up to the end of life Dr. Jackson was ready to listen to any new suggestion that was likely to be useful. He was most punctual in his appointments, and always endeavoured to visit patients at the hour he was expected, and so avoid much anxiety to a nervous patient and anxious family.

He did his best to produce and maintain a spirit of harmony among the medical community. He endeavoured to see the good points in everybody's character, although he did not love them. These are certainly qualities worthy of the highest member of a noble profession.

I fear we are too ready to think that the bounds of medical ethics are only strained by those members who descend to advertise their wares by placarding their windows with "*Advice and Medicine Six-pence.*" The price charged can surely not affect the principle. The consultant who charges his guineas for a prescription for drugs which are unnecessary and therefore harmful, as well as the general practitioner who measures his day's work by the number of bottles he makes up, and the boxes of pills he sends out, are none the less flagrant offenders against the ethical principles that Holmes contends for. If every medical man asked himself seriously before administering a drug if he conscientiously thought it essential, what a stagnation there would be in the drug-market, and shall I venture to ask it,

what untold benefits to the poor patients? Over-drugging, I fear, is the universal besetting sin of our profession. It is time that we should do our part to remove what Holmes calls the disgrace of medicine due to "a colossal system of self-deception, in obedience to which mines have been emptied of their cankering materials, the vegetable kingdom robbed of all its noxious growths, the entrails of animals taxed for their impurities, the poison-bags of reptiles drained of their venom, and all the inconceivable abominations thus obtained thrust down the throats of human beings suffering from some fault of organisation, nourishment, or vital stimulation."

In several places Holmes hints as to the necessity for a doctor to adhere closely to his profession, and in Valedictory address in 1871, he says: "I warn you against all ambitious aspirations outside of your profession. Medicine is the most difficult of sciences, and the most laborious of arts. It will task all your powers of body and mind if you are faithful to it. Do not dabble in the muddy sewer of politics, nor linger by the enchanted streams of literature, nor dig in far-off fields for the hidden waters of alien sciences. The great practitioners are generally those who concentrate all their powers on their business."

Some of you, perhaps, may more fully agree with Dr. Holmes in reference to this point than I do; but while I do not advocate medical men following the example of the eccentric Parisian, Charles Cros, who touched everything, from politics to potatoes, and from the differential calculus to cauliflowers, I am not disposed to deny the right of medical men to undertake the duties of citizenship. Indeed, I think that they might render yeoman service if they were prepared to undertake municipal duties in large towns; and, even in political life, if they could divest themselves of blind partisanship, they might often help on progressive movements. There is surely a period in medical life when we can dispense with the help of the "bottle," and live a fuller and more vigorous life. And I cannot see why we should be one whit less useful in our medical capacities if we took a lively and rational interest in the movements which excite the attention of the best minds of our times. First and foremost, by all means, let us be worthy members of our calling, but at the same time let us not ignore our duties as worthy citizens and useful residents of the locality where our lines have fallen.

I shall conclude this paper by reading portions of Holmes' poem recited before the National Sanitary Association in 1860:

What makes the Healing Art divine?
The bitter drug we buy and sell,
The brands that scorch, the blades that shine,
The scars we leave, the "cures" we tell?

Are these thy glories, holiest Art,—
The trophies that adorn thee best,—
Or but thy triumph's meanest part,
Where mortal weakness stands confessed?

Though on the field that Death has won,
She saves some stragglers in retreat;
These single acts of mercy done
Are but confessions of defeat.

What though our tempered poisons save
Some wrecks of life from aches and ails:
Those grand specifics Nature gave
Were never poised by weights or scales!

God lent his creatures light and air,
And waters open to the skies;
Man locks him in a stifling lair,
And wonders why his brother dies!

In vain our pitying tears are shed,
In vain we rear the sheltering pile
Where Art weeds out from bed to bed
The plagues we planted by the mile!

Be that the glory of the past;
With these our sacred toils begin;
So flies in tatters from its mast
The yellow flag of sloth and sin,

And lo! the starry folds reveal
The blazoned truth we hold so dear:
To guard is better than to heal,—
The shield is nobler than the spear!

THE BEGINNINGS OF DISEASE.[1]

By H. Campbell Pope, M.D. Lond., F.R.C.S.,
President of the West London Medico-Chirurgical Society.

It seems but as an interval of four or five summers since we first, in our corporate capacity, met in this room under the presidency of Dr. Vinen, by the kind permission of the authorities of the West London Hospital. But reference to our records assures us that seven long years have passed away since that day, and we have consequently gone through the most trying portion of our infancy, and have now to enter upon a period leading up to adolescence, in which it behoves all of us to see that the promise of our early years is progressing steadfastly towards fulfilment. I feel that in entering upon this second period much honour and great responsibility have been laid upon me, while still a junior in our profession, by your kindness in installing me as the occupant of this chair, for which I most sincerely thank you, and I beg leave to still further trespass upon that kindness by asking you to put down all my shortcomings rather to lack of experience and capacity than to want of devotion to the objects and interests of this growing society.

Our last session was full of interest, and marked by steady progress under the fostering hand of our last president, Dr. Travers, whose ripened judgment, genial manner, sincerity of purpose, and methodical conduct of business, have given to his presidency an enduring title to remembrance. Since our last meeting our pleasant recollections of the vacation are marred by the removal by death from our ranks of one of our members (Mr. Samuel Benton), who took great interest in the society, and enriched its proceedings by papers and contributions to debate.

In opening our session I beg to cordially congratulate the society and its founder, Mr. Keetley, on our continued increase in numbers, and to express the hope that the nature of our work and the varied features of our evenings may attract year by year still greater numbers of earnest students of our art, to our mutual edification, and to the extension of our public usefulness.

It is no slight matter for one engaged in general practice to select from amongst the multitude of subjects which engross his attention any one in which he is so well versed as to justify his addressing upon it such an audience as this which contains those who have paid special care to almost all the sub-divisions of professional knowledge.

But the nature of our labours, whilst not allowing us opportunity to study minutely the diseases of special organs, gives us this advantage over the specialist, that we are enabled to have an outlook over disease of a much more extended range, that we can often follow the life-history of our patients from the cradle to the grave, that

[1] An address delivered before the West London Medico-Chirurgical Society, at the opening of the Eighth Session, on Friday, Oct. 4, 1889.

we can see the interdependence of diseases, by reason of a wider and more intimate knowledge of family history, and above all that we are privileged to witness and take note of those early departures from a healthy standard, which constitute the "beginnings of disease." I say privileged, because it is in these early stages of various maladies that it is possible not only to afford present relief from them, but often also to indicate their causes with a view to prevention in the future.

In taking, however, this title to my address, no one is more sensible of the insufficiency of a single paper to do justice to such a theme than myself, or of the still greater inadequacy of an ordinary practitioner to speak upon it. However, this much by the way of apology should be stated, that we of the rank and file are called upon to treat disease in all its protean forms; that by experience to all of us comes some method of dealing with it; that the opportunities of giving public utterance to the faith that lies within us are few; and that when such opportunity does come to one of our number, it is his duty to examine his line of practice and summarise his views that whatever grains of truth they may contain shall not be lost. And, indeed, it is the conviction that much knowledge of inestimable value to mankind is lost by a want of system, and a ready method of collating experiences among general practitioners which has mainly led me to address you this evening on the "Beginnings of Disease." Having this object in view, it is necessary to suggest a method by which such knowledge may be made available for scientific purposes, and the germ of such a method I hope presently to bring before you for consideration. But previously to so doing, it is necessary to state what is to be understood by "beginnings of disease." Dr. Andrew, in his admirable Cavendish Lecture this year, says, "All disease begins mediately or immediately in the environment," and he proceeds to quote from Dr. Harry Campbell's learned work upon the "Causation of Disease,"[2] a still more emphatic statement—namely, "The environment is in the last resort the sole cause of disease," which is followed by a short explanatory statement.

For the purpose, however, which I have in view this evening, it is necessary for me to examine into the causation of disease much more fully, on the lines laid down in Dr. Harry Campbell's masterly work, to which I must express my great indebtedness. This work considers the *general* origin of disease; for our purpose, it will be better to consider disease as affecting any individual. The "Beginning of Disease" then in any individual, may be from the moment when the male and female elements of which he is composed have united to commence the developmental process. This is what is meant by "beginning" as we consider it to-night, let us see what is meant by disease. Disease is a process occurring in a *living* being, or organism, and will so be considered as belonging to *life*. Life in a normal state should be pleasant and easy, that is, not obtrusive on the consciousness; disease or uneasiness shows that something is wrong or abnormal, and may thus be defined as "abnormal life." We must now consider what is life, and then what conditions make it abnormal, or subject to disease.

Life is best studied with a view to definition in its simplest form, the simple cell, which lives so long as certain interactions takes place between it and its surrounding medium or environment. Life is the result of a series of interactions between an organism and its environment, which interactions may be normal and orderly, or abnormal and disorderly. In the first case we have normal life in which the organism and the environment are suited to one another; in the second case we have abnormal life or disease, in which the organism and its environment are at variance, through the fault of the organism in its structure, or through unsuitability of the environment to the structure of the organism, or through faults in both. Now the life which we as medical practitioners have to study, is not so simple as that of the amœba floating in the drop of water, it is a life of infinitely more complicated structure, consisting not of one cell, but of millions, arranged into specialised organs and tissues, carrying out duties and functions subservient to the life of the whole structure; each cell, and each organ or tissue, having its own special environment, and the whole body or structure surrounded by an environment, complex beyond description and differing for every individual.

But this is not all, every cell is composed of a protoplasmic material, consisting of untold numbers of atoms compounded into molecules, of molecules formed into structures of infinite variety, agitated by dynamic movements, and exhibiting chemical changes, of which, at present, our knowledge is rudimentary. How then can we best study these interactions of organism and environment? First by understanding the nature of organism and environment, and then by seeing how these two factors mutually react. Dr. Campbell very conveniently uses symbols—(S) for the structure of an organism; (E) for the environment—thus, S + E = life.

Let us consider the nature of the environment of an individual calling it E.

E is of two kinds { *a*. Internal-cell E. *b*. External-body E.

(*a*) INTERNAL-CELL E which consists of the nutrient plasma which surrounds the cell, and feeds it, and has returned to it the excreta. This plasma then must be kept pure and fit, both by what goes into it, and by the removal of effete matters from it. We must here remember that one set of cells can influence the E of another set, or of the whole body. Thus we have inefficient kidney action, allowing nitrogenous excreta to remain in the plasma, injuring the action of other cells, say of the brain, or even poisoning the whole system. Digestive disorder or alcoholic excess will supply impure plasma. Imperfect respiration, from whatever cause, will give rise to the retention of noxious matters. Exterior violence, great atmospheric changes, microscopic organisms, noxious gases, and many other causes which will readily occur to you, notably, the direct influence of the nervous system on secretion, excretion, and body heat, and indirectly through the operations of the mind, can all powerfully affect the production of this plasma, and consequently the cells of which it is the environment.

(*b*) EXTERNAL BODY, E.—Darwin divides external body E into organic and inorganic. The organic consists of the community of organised beings by whom we are surrounded. The inorganic consists of the telluric and atmospheric influences, sunlight and exercise. Campbell speaks of the physical and mental environment.

Contrast for one moment the physical and mental environments of a literary man and a dock labourer, and think of the effects of their respective environments on their mental and physical conformation. Diversity of environment tends to make perfect adaptation of structure

[2] "The Causation of Disease," by Harry Campbell, M.D., Lond. H. K. Lewis, London, 1889.

to it impossible, except several generations are exposed to a more or less similar environment.

The adaptation of an hereditary line to a special environment is best shown in the Bach family, whose adaptation to their musical surroundings culminated in the production of that great genius, John Sebastian Bach.[3] Veit Bach, a German baker, resident in Hungary, was forced, by religious persecution, to seek a new home in Germany. He settled in a village near Gotha, and played the lute at his mill while his corn was being ground. He had two sons, Hans who became a musician, and a second son who became a carpet maker, leaving three sons, all of whom became musicians. Hans Bach had also three sons—organists—the youngest of whom, Heinrich, was highly esteemed as a composer. Heinrich had four sons—musicians—one of whom was the greatest organist of his time. The brother of Hans Bach, Christoph, had three sons, of whom two, John Ambrosius and John Christoph, were twins. The twins were exactly alike, so that their wives had difficulty in distinguishing them, and they resembled each other as much in speech, tastes, and disposition, and in their style of music, as they did in outward appearance.

When one fell ill so did the other, and their deaths followed each other closely. One of these twins, John Ambrosius was the father of John Sebastian Bach. At the time when Bach's fame was highest, nearly thirty of his family held posts as organists in Germany, and they met once a year to exercise their talents together. Sir Julius Benedict says "it would be very difficult, if not quite impossible' nowadays to find a man of the stamp of J. S. Bach free to follow the bent of his genius untrammelled by the continuous troubles and miseries of life."

Here we have a history of four generations exposed to one environment—viz., church music, leading up to the production of the greatest genius of his kind, which is as much as to say perfect adaptation to environment. You will pardon this somewhat long example, as it will also serve when speaking of structure. "Given healthy structure evil can only come through environment."

But it is time to speak of structure: how does it come about? Through the operation of heredity and environment. In sexual heredity the offspring tends to be produced as a *certain mean of structure* of the parental structures, the males tending to one type the females to another. Now were heredity untrammelled, the result would be that in a family all the boys would resemble one another, as would also the girls.

But the action of environment comes into play; the action of it on the germ and sperm cells is different for each successive child before they come into union at all, and after they have united and the organism is started on its career there is the action of environment to be considered both before birth and after. Now this environment cannot be the same in any two cases, and hence arise "natural variations."

What is truly hereditary in the structure of any individual is the result of the combination of the germ and sperm cells at the time of their union. After the union has taken place and development commenced, environment helps in influencing the structure. There will be, then, two different periods to consider—before, and after birth. Before birth, that is during intra-uterine life, the growing child may be influenced by the mother's blood and by pressure. The mother's blood may be altered in quantity or quality. You will have noticed as a rule that a large placenta accompanies a well-developed child, and *vice versâ*. The quantity of blood, then, seems to be important. But how much more so is the quality! how many diseases commence in intra-uterine life from altered quality! To take two into notice will enforce this point—syphilis and rheumatism. Again, external pressure may influence the child in utero, twistings of the cord and pressure at birth. It is difficult to see how the so-called "mother's marks" can be produced through the mother's blood; arrests of development can be imagined to occur from external injury, but in all these cases it is far more likely that the initial fault is in the germ or sperm cell, or both, and that the frights and alarms which are generally forthcoming to account for such events are coincidental and not causal.

Nevertheless, it is not possible to deny absolutely that there is any force capable of acting to produce these results through the medium of the mother's nervous system, and all cases of so-called mother's marks and malformations are worthy of careful study.

And here, before entering upon the action of environment in modifying structure after birth, a most important principle must be attended to—namely, that "*environment is potent in modifying structure in proportion as it acts early in the life of the individual.*" How important then to the infant that its environment should be healthy, that it should be supplied with its natural food, the mother's milk, that its respiration should be carried on in pure air, and unimpeded by unyielding swathes; that the minor rythms of life, sleep, exercise, and the action of the bowels, should be set going as it were, to keep their regular times.

But I am not about to speak of the management of children, as that involves points of daily practice known to all of such audiences as this, and I am *now* more concerned with principles; on one matter only would I, in common with Dr. Campbell, lay great stress, that is, the constant examination of the excreta of the bowels, for intestinal catarrh is the beginning of a legion of diseases. And as growth proceeds, the question of education comes in, for the mental structure is largely determined by this; if wisely directed, in other words, if the mental E is adapted to the mental S, we shall get healthy growth, if not, we may easily get unhealthy interaction, and the "beginning of disease." How great is the responsibility of our State-educationists in putting all kinds of structures through one mental mill; is it not a certainty that disease must begin in a greater or less number of growing organisms so treated? And the training of moral sense and the will is most important, for as the individual approaches adult age he may have to choose his own environment, whether he takes up his abode in a crowded city or the open country; whether he contracts habits which will evolve his constitution and his character, or involve them in the dissolution of disease; whether he transmits to posterity, in accordance as his choice is made, an inheritance of weal or woe; whether he, as forming part of the environment of his neighbours, is clearing the moral atmosphere, or imparting to it a poisonous miasma; whether, in short, he is helping in the evolution of his race, or falling under the iron rod of natural selection.

But more must be said of the part which heredity itself takes in forming structure, and time will not allow much to be said upon this tempting theme. It will be remembered that heredity was spoken of just now, as producing in the offspring a *certain structural mean*, that is to say not always an exact structural mean. There will be "pre-potency"

[3] "The life of John Sebastian Bach," Houlston and Sons, Paternoster-quare, 1876.

of some characteristics of the male or female parents; thus there will be an infinite number of blendings, which fall into three groups:—

1.—Physiological blendings.

2.—The blending of the normal with the abnormal.

3.—The blending of the abnormal with the abnormal.

This subject is fully discussed in Dr. Campbell's work, and is deserving of minute study.

In these blendings a great variety of diseases take their rise; but on the other hand, in the case of the union of the normal with the abnormal, the abnormality may be neutralized, and the offspring brought forth free from a disease possessed by one of its parents, being in fact a *reversion* to an ancestral type free from this disease. This, however, could only occur where the disease or peculiarity had been of comparatively recent age, for those characters as a rule are neutralized which are of recent growth; the greater the age of a structural peculiarity the greater its stability.

In like manner the latest acquirements of the parents are the least likely to be transmitted. The progress of disease shows a somewhat similar law, the latest acquired parts are the first to suffer—that is, have the least stability; for instance, the nervous system, the most highly-evolved structure, is the first to respond abnormally to a mal-environment; and again, the most recently-organized part of the nervous system is, in insanity, the first to show signs of dissolution, wherefore as a beginning of insanity look for some perversion of the moral sense. The law of heredity, then, prepares us to expect like characters to appear in the same sex in the offspring, and generally in the same period of life. But a character hereditarily transmitted may not show itself as an *actuality* in the offspring of opposite sex, but is nevertheless *potentially* present, and may be transmitted through that sex, to appear as an *actuality* again in the original sex.

The phenomena of hæmophilia are evidences of this; and we may, therefore, in studying the family history of a male patient find traces of his disease in his maternal grandfather's constitution, and this involves questions of some moment in estimating disease chances in the examination for life insurance, where the "beginnings of disease" are not infrequently brought prominently under our notice. It is impossible in such a paper as this to notice in any adequate manner the phenomena and bearings of this great question, but the main facts of heredity are known to most of us, and therefore I will only further enlarge upon this subject when considering the morbid interactions of structure and environment. To sum up, it is to be remembered that heredity under a similar environment tends to produce individuals whose structure is a certain mean of the structures of their parents, and resembling that of one another, save for differences of sex. The Bach twins John Ambrosius and John Christoph were formed under as similar an environment as could be well imagined, and the result has been given above—namely, that they resembled each other not only in outward appearance, but to the utmost reach of their development, as shown in the same musical expression of the immaterial conceptions of their minds. Nature could hardly have given to the world a more perfect example of the workings of heredity and environment in the causation of structure. Structure is then due to heredity mainly, but subject to the modifications of environment both before and after birth.

And now having grasped the nature of S and E, we are in the position to examine their morbid interactions in the production of disease. Let us revert to the formula S+E=healthy life, which presupposes that S and E are normal. Unfortunately we have no criterion of the normality of S and E except the result of their interaction. If this result be painless, happy life, till the organism has finished its rhythm, and ceases its interactions because its course is run, then S and E have been normal to one another.

Let S represent a literary man of slight muscular development, and let E represent his accustomed sedentary work and mental surroundings. We will suppose him to have inherited an average structure, and that his immediate surroundings are free from glaring sanitary defects. We shall here get a fairly normal interaction, and a fairly healthy life. But place this S (the literary man) in a fresh E, let him take his place in the blacksmith's smithy for a week, if he has not by the end of that time strained his cardiac valves, or ruptured himself, he has in all probability, from the exposure to great variations of temperature, contracted some catarrh or inflammation. Here S + E = abnormal life or disease. It is then best to speak of this as abnormal—E, so far as that particular S is concerned, we thus get S + abnormal E=disease. Similarly by reversing our example, and putting the blacksmith in the student's library, we might in the same time find him suffering from hæmorrhoids, or exhibiting signs of inhibitory paresis, such as restlessness and the use of unparliamentary language, even if mental alienation had not already occurred. But on the other hand these structures are also abnormal to their changed environment—that is to say, S and E are *both* abnormal one to the other.

Dr. Campbell sums up these points thus: "*If the S is so constituted that healthy vital interaction is impossible under any conditions of E, that S is absolutely and inevitably abnormal; and, conversely, if an E is such that no S can respond healthily to it, that E is absolutely and inevitably abnormal.*

But if a set of conditions exists in which the S can act healthily, that S must be regarded as possessing, at all events, a potential normality; and, conversely, if there is a set of conditions to which some invidiuals are capable of responding healthily that E is normal to them."

We cannot do better than give attention to these several statements. Is any S so constituted that healthy vital interaction is impossible under any condition of E? Is there any S absolutely and inevitably abnormal?

In speaking of the cause of structure it will be remembered that heredity was the most potent factor, and afterwards environment, in direct proportion as it acted early in life of the individual. Hence we may expect to find the frailest structures owing their defects to hereditary causes, or the action of environment in intra-uterine or very early *post-partum* life. Examples of structures so constituted from pure heredity, that healthy vital interaction is impossible, are rare, but are to be found. Those born of parents with advanced phthisis, and children of the third and fourth generations of dwellers in the central parts of large cities, or those suffering from malformations in vital organs. More common are those whose defects have arisen before birth from a mal-environment, say from the syphilitic poison, some of whom cannot survive even up till birth; or again, say, those whose hearts are crippled by intra-uterine rheumatism; or those in whom the brain has been so injured during labour that long survival is impossible.

And again many structures are so ruined during infancy, by malnutrition consequent on improper feeding, followed by prolonged diarrhœa, rickets, and resulting nervous diseases, that they are unfitted to exist even in the most favourable environment.

Then we come to consider the inevitably abnormal environment. Some E's are *necessarily fatal*, such as certain poisons and traumatic injuries, starvation, and deprivation of oxygen. Apart from these, however, are various environments in which no structure can live healthily, and which, by their influence on structure, will become *necessarily fatal* in the third or fourth generation of those exposed to them. Such are excessive use of alcohol, residence in the crowded areas of large towns, and exposure to insanitary influences in other ways. Certain occupations are necessarily abnormal, and confinement to close rooms and lack of exercise, will soon affect the strongest S.

But it is not to be considered that because a structure responds abnormally to a certain E, that it is *impossible* to find an E to which such a structure can respond healthily, and on the other hand an environment which is abnormal to the many may prove normal to a few. "What is one man's food is another man's poison."

To suit such structures with environments normal to them becomes then a practical task for the physician, and the practical value of the views we have been considering, consists in our being able to apply them to our daily work.

Now the symbol S standing for structure, expresses very well the value of S as derived from heredity only, it cannot express those after-effects of environment on structure, which occur during *ante* and *post-partum* life, and it is evident that much of the structural proneness to disease is contracted in these periods, and ought to be valued, in considering the interactions of S and E in producing disease. This factor may be expressed by s, and then Ss would represent the structure of an individual as compounded by heredity and environment. $Ss + E =$ disease.

Now, if we wish to make use of this formula in estimating the part which each factor takes in determining disease, we must attach numerical values to them.

Omitting s for the present, that is, the relative proportion of one of the factors of structure to the other, in the consideration of the interaction of S and E, we find, following Dr. Campbell, that it is convenient to suppose a given disease to be made up of eleven units, and we get a series as follows:

a. $S_{10}+E=11$	*e.* $S_6+E_5=11$	*i.* $S_2+E_9=11$
b. $S_9+E_2=11$	*f.* $S_5+E_6=11$	*j.* $S_1+E_{10}=11$
c. $S_8+E_3=11$	*g.* $S_4+E_7=11$	*k.* S_0+E_{10}
d. $S_7+E_4=11$	*h.* $S_3+E_8=11$	

(pp. 164-165, "Causation of Disease.")

a. An individual in whom the disease bursts out spontaneously.

k. An individual in whom the largest quantity of specific pathogenesis is unable to produce the disease.

These are the two extremes of the scale. Dr. Campbell gives the following illustration of his method: "Let us apply this numerical method to illustrate the share in causation taken by S and E respectively in a particular disease—*e.g.*, insanity. "It must be borne in mind," says Maudsley, speaking of the causation of insanity, "that hereditary predisposition may be of every degree of intensity, so as on the one hand to conspire with certain more or less powerful causes, or, on the other hand, to suffice of itself to give rise to insanity, even amidst the most favourable circumstances." Let us endeavour to give numerical expression to these words of Maudsley. The formula $S_{10}+E$ signifies that, under the most favourable E, the individual will become insane; S_9+E, that, with the greatest conceivable care, the disorder may be averted. . . . It would, of course, be possible for the disease to be called forth by a more powerful exciting cause—*e.g.*, E_5; but in such a case the excess of E (three) is in a manner inoperative. For speaking, as we are, of the pathogenesis of insanity, without any regard to the *intensity* of the morbid action, we cannot get more than 11, since this number represents the full disease.

No doubt a greater quantity of specific mal-E—*e.g.*, prolonged mal-hygiene—might induce a more intense attack of the disease, but I am not attempting to represent numerically the *intensity* of the disease; I am dealing only with the actual presence or absence thereof, the number 11, or any higher number, denoting the presence of insanity, the numbers below this its absence. It would, perhaps, be possible, however, to somewhat roughly denote in this numerical way the intensity—the *dose*, if we may so put it—of the malady."

Now, in estimating the part played by structure in these interactions of disease, it is better, if possible, to apportion to small s its value; thus, if a structural proclivity be estimated at six, and we consider that four parts are due to heredity, and two to environment, acting on the structure in the past, we may express the equation thus—$S_4s_2+E_5=$ the causation of the given disease.

There are many subjects in connection with these interactions which I would willingly have alluded to, but the limits of time forbid, and the influences also with regard to disease, of natural selection, sexual selection, and the direct action of environment, must be left untouched.

But I fancy some one of my hearers who has been brought up in the modern school of thought is saying, "all this have I known from my youth up," and the man of practice cogitates how that it will all end in pulv. jalapæ co., tinct. ferri, and cod liver oil, and both perhaps are thinking "cui bono" are all these theories. Unfortunately, the cogitations of our practical friend prove often only too true, and we often have to prescribe these remedies, where our reason tells us that what is wanted is wholesome food, maternal care, and ocean breezes.

However, there is truth in these theories, and such truth as there is will prevail; meantime, let us consider how they can be turned to practical account by this society. In a changing population like this what an immense advantage it would be to us practitioners, and to our patients what an inestimable boon, if, when they came to see us for the first time, they brought a card duly filled in by some qualified practitioner, containing particulars of their family history as far as could be obtained, of their own life history, including what diseases they had suffered from, and what influences they had been subjected to, and of any idiosyncrasies with regard to drug action or proclivity to fevers. Such details would put us at once *en rapport* with our patient, and much blind groping and feeling of the way would be avoided. I should like for this society to lead the way in this matter, and for it to appoint a small committee to draw up a card, so arranged that it would show at a glance the structure and the previous environment of a patient. The card should be in the patient's possession, a corresponding card or counterfoil being kept by his medical attendant. These counterfoils would soon, if used by a large number of practitioners, represent an amount of experience which is now almost lost, in that it dies with its possessor. It might in time be worth the while of Government, when it has a Ministry of Public

Health, to devote an office to the collation and classification of these facts, and the issue of such cards to the Army and Navy Medical Departments could not fail to bring much valuable information to light. I hope the society will seriously consider this question of appointing a committee to prepare such a scheme; it would, by thoroughly carrying it out, be the first to till in the interest of science the fallow and yet fertile field of *general* practice.

And now, as "example is better than precept," let us proceed to examine a case on this basis of structure and environment. We have a young man to advise who is suffering from incipient phthisis; his father died of this disease, but there is no other history of it in his family. He is living in London, and his habits are more of the town than the country, but he is well off, and we have *carte blanche* to advise him as we deem best. He has not altogether led a steady life, and he is decidedly getting worse.

Let us consider S first. His father died of phthisis; at what age? At forty. He first showed signs of the disease at thirty-five. Our patient is twenty-five, he is already showing signs; here then is considerably hereditary tendency, let us say S_4; but he has not been steady, and he has lived much in town, and he begins his disease ten years before his father; his environment has affected his structure to the extent of quite two units. His structure then may be represented by $S_4 s_2$, and his equation will be $S_4 s_2 + E_5 = 11$. This is serious, and matters are growing worse, he must be sent to Davos; that is the thing to do, say all his friends.

This is a radical measure indeed; truly a change of environment; what we are concerned in, is, will it suit him? Here is a Londoner living, not so much above the sea level, in a damp-laden atmosphere and dusty, but he loves his London life, and he cares not for reading, or the dulness of the country. But at Davos he will have tobogganing, and skating, and private theatricals, and books, and the glorious scenery, and the mountain air, say the friends. So he will, but before all he will have to obey the doctor's orders, and we are doubtful if the restraint and the change of life will not do him more harm than good, by making him hypochondriacal, for the doctor will not let him *run risks* to amuse himself, and for scenery and books he cares not one jot. And what is his physical condition? and what cases are unfit for high altitudes?

The chief contra-indications are, undoubtedly, an excitable nervous temperament which, under the stimulating influence of high altitudes, gives rise to intense irritability and sleeplessness. Extensive emphysema, pneumothorax, and hydropneumothorax. Valvular lesions, present hæmoptysis, high temperature or breaking down of the lung. Well, our patient is sent there as he presents none of these symptoms in a marked degree, and we have the more confidence in sending him to Davos as one of our own members, Dr. W. R. Huggard, is there, practising, and most worthily sustaining the reputation of British medicine. This is the line of thought which should be followed in working out a case in the manner suggested.

As regards Davos, an excellent paper was written by Dr. Clifford Albutt, in the *Lancet*, vol. ii., 1888, p. 704; and Dr. Huggard's valuable opinions will be found in the *London Medical Record* for June, 1886. When in Davos this summer, Dr. Huggard told me he considered no small part of the benefit of highly rarefied air was due to its causing increased depth of respiration, calling into play portions of the lungs often unused, this he called "lung gymnastics." The journey to Davos is now greatly shortened in time, by the extension of the railway from Landquart to Klosters, and the valley is magnificently illuminated at night by the electric light. And here let me clearly indicate what is aimed at by a residence in Davos—it is nothing less than a permanent change of structure by the action of environment; this takes time, and let no one with a light heart send a patient for this cure, who cannot stay until he is cured.

The breaking up of a home in England, if it is the breadwinner who is affected, and the casting of the whole fortune on the hazard of a single die, is not to be taken without grave reflection; for if the sufferer has to return before his structure is consolidated, he will come home with diminished fortune, to begin life again, and with the almost certainty of a relapse through added worry, and the action of the old environments.

But our patient, we will suppose, has been "cured," and may leave the high altitude, and now comes a question nearly as important as was raised before—is it safe to send him straight home? I do not think so: to go direct with a newly organised structure of a lower resisting power, from highly rarefied, pure, cold, air, to the warmer, muggy, smoky atmosphere of London, is a crucial experiment which it is unwise to make. It is better to halt at a lower elevation, say from 2,000 to 2,500 feet above sea level, and gradually accustom the lungs to the increasing pressure. Patients on leaving Davos not unfrequently suffer from catarrh on reaching the low level, and the danger of this needs no pointing out. Now as an example of such a halting place, I would mention Heiden, in the canton of Appenzel, East Switzerland. This village is not difficult of access, from the Engadine *viâ* Chur to Rorschach on Lake Constanz, and thence to Heiden by the picturesque Rorschach-Heiden mountain railway. This charming place, situated among the sub-alpine meadows at the foot of the Sentis, 2,645 feet above the level of the sea, surrounded by pine woods, and overlooking Lake Constanz, commands a magnificent panorama across the lake ranging from the Vorarlberg Alps in Austria on the south-east; to Baden on the north-west. Here you meet few English travellers; but the German doctors send many patients to brace them after the courses at Carlsbad, Marienbad, and Kissingen. Through the kindness of one of the local practitioners, Dr. Altherr, I am enabled to furnish the members of the society with some particulars which will enable them to judge of the climate of Heiden, which was highly recommended by Niemeyer and Von Graefe.

Heiden has a sub-Alpine climate, with a moderately cool temperature (sommerfrische). The air is aromatic, very pure, rich in ozone, and almost absolutely free from dust. The mean barometric pressure in summer is 693.5 mm. = (27.25 inches). The average temperature is, in May, 45.5 Fahr.; June, 57.5; July, 63.8; August, 58.4; September, 53. The relative moisture is, in May, 90; June, 67; July, 66; August, 66; September, 76. This shows a very dry air; owing to the open position of the village, a permanent current of air exists without causing harmful draught. Great daily changes of temperature are seldom felt in Heiden, nor does the intense valley wind felt in the upper Alps exist there. Therefore, the air is in a high degree bracing, and neither tiring nor exciting. The remedies used in Heiden are milk drinking, goat's whey drinking, and bathing, and hydrotherapy.

The whey-cure is a celebrated old remedy, at one time

nearly lost sight of, and then revived. It is prepared from goat's milk, and is a very easily digestible nourishment; a little casein and albumen are contained in it, and much sugar of milk—53 parts in 1000; also blood salts, especially those of potash and soda. The whey helps tissue change; the urine is increased in gravity and quantity. The action on the intestinal canal varies with individuals. The secretions of the mucous membranes, especially of the lungs, stomach, and kidneys, are increased. Through this quickening of the tissue changes, the constituents of the blood are renewed more rapidly, therefore the blood is improved.

The indications are:—Chronic catarrh of the larynx and bronchial tubes, gastric conditions accompanied by habitual constipation, congestion of the portal venous system, catarrhal affections of the bladder, hæmorrhoids, chronic Bright's disease, and anæmia of young people. The contra-indications are:—Hæmophilia, diarrhœa, advanced phthisis, atony of the stomach, and universal degeneration of the nervous system.

Since 1886, Heiden has had a high pressure water supply. The water is very pure and fresh, temperature 37.5 Fahr., therefore it has been possible to set up a small but elegant hydropathic establishment, fitted with the newest douches and bathing appliances.

It will be seen from Dr. Altherr's report that Heiden is good for many "disease beginnings." For my own part, I believe that few places are so suitable for the neurasthenic patient as this: the calming effects on the irritable nerves are great; no fatigue is felt; a fresh walk, without tiring effect, might be taken daily for months; the sanitary arrangements are good, and the British Philistine is unknown. Much of the good effect of the whey-cure I believe to be due to the early rising, enforced exercise, and regular habits which its use entails.

It was my original intention to contrast the expected effects on our supposed patient who was sent to Davos, with the efforts which might be anticipated by sojourn, say at Hyères, with a sea-side atmosphere of high pressure. Dr. Sawtell, of Costebelle, near Hyères, very kindly supplied me with materials for so doing, but time will not permit, and if my hearers are interested in this subject and method of investigation, they will find their data in a paper written by Dr. Sawtell for the *Illustrated Medical News*, and published in that journal on September 9th, 1889.

We will now suppose our patient having completed his cure has left Heiden (where catarrh is almost unknown) and come home. Here, perforce, we must leave the consideration of him. But I must still crave your attention a little longer (and I fear I have trespassed on your patience too long), for we have only been considering the case of one of the elect among sufferers, one so blessed with this world's goods that he could change his surroundings as he was advised. In fact, we have been considering *individual* environment; but what about the *social* environment! what about the thousands who are left in *London alone*, deprived of the conditions by which they can retain their health. True it is that the law of evolution will weed them out, and also true that if we patch them up, we are interfering with one of Nature's laws, and delaying her operations for the perfecting of her work.

But patch we must, and in so doing we learn more and more of Nature's laws, and by collecting our knowledge and analysing it we may help to hasten on the time when even civilization can be furthered in accordance with those laws, instead of being, as it is now, advanced in direct opposition to them. For what are we doing? poisoning the atmosphere, which should give us bracing life; poisoning the rivers, which should be pure to slake our thirst; poisoning our bodies with adulterated food; poisoning our blood with syphilis and drink; starving our minds by veiling Nature's face and hiding from her presence, and as we reap a copious harvest of "disease beginnings," forsooth, we marvel at the cruelty of Nature, and of Nature's God.

A possibility, however, has arisen, now that we are under a new municipal government, that some of these evils will be abated; more air and light may be let in to our great towns by carrying large boulevards through our crowded places; the amines process of sewage treatment gives a chance of purifying our larger rivers; while the Smoke Abatement Act, the Food Adulteration Act, the Contagious Diseases Acts (uniformly administered), the encouragement of temperance, and of the knowledge of Nature's work, are all means to effect such changes in our cities, that health and happiness may confidently be looked for, where at present disease and misery hold sway. For if environments be not *necessarily fatal* an ultimate adjustment of S and E may be obtained.

Of one only of these agencies will I speak, as it promises the mitigation of one of our most troublesome environments—the presence of zymotic germs. Zymotic germs form very dangerous environments, on account of their variable nature; by this I do not mean their varied nature. Germs are living organisms, and therefore vary according to their own environments; thus epidemics vary largely in severity in different localities, and in the same locality at different times. It is indeed probable that we are more susceptible to germs of disease arising out of our own neighbourhoods. It a well-known fact that the negro who lives with impunity in his ague swamp is highly susceptible to various fever germs in this country; while, on the other hand, the medical man who might visit unscathed in London fever dens, would be at once laid low on the West Coast of Africa. Zymotic diseases play most havoc when different tribes or nations come into contact for the first time.

A more homely instance will perhaps also give point to this; my own children, who are constantly somewhat exposed to disease germs, have had no zymotic illnesses at home, but have suffered from three different varieties contracted during their annual visit to the sea. The immunity of doctor's families has often been commented on; I think the explanation will be found in the adaptation of S to E. Their structure and environments become normal to one another.

In large cities the sewage always contains more or less disease germs, potential epidemics, and to find means to make sewage innocuous has been one of the aims of sanitarians for many years. This however has apparently been accomplished by the invention of Mr. Wollheim in the "Amines Process" of sewage treatment. A full account of this process will be found in the periodical *Iron*, of Sept. 20th, 1889. The process consists of treating sewage with a mixture of herring brine and lime; herring brine contains trimethylamine and propylamine, and by the action of lime on these a gaseous body is given off, to which the inventor gives the fanciful name of "aminol," This is fatal to germs of all kinds. Neither lime nor herring brine alone will produce this effect. Dr. Klein, who has several times

examined the effluent, both from experimental trials at West Ham and Wimbledon, can cultivate no germs from it, and he says, whereas London drinking water contains 1,525 organisms per cubic centimetre, the effluent contains none. Not only so, but the sludge undergoes no decomposition, though exposed for weeks to sun and showers. Our County Council will do well to give this process a thorough trial at Crossness, for by its action we may have restored to us our Silver Thames, and be greatly helped in stamping out zymotic disease. This question of disease being so largely caused by environment requires ventilation, and will doubtless in time permeate the intelligence of the community, and in this permeation we may largely help, for as we have seen, one collection of cells can influence the environment of other collections of cells, or even of the whole body, so we, as centres in the social organism, can duly play our part.

The action of S and E was perceived years ago by that great student of nature, Victor Hugo, who wrote: "We die undermined as well as stricken down. Let us not weary of repeating it, to think first of all of the outcast and sorrowful multitude, to solace them, to give them air, to enlighten them, to love them, to enlarge their horizon magnificently, to lavish upon them education in all its forms, to offer them the example of labour, never the example of idleness, to diminish the weight of the individual burden by intensifying the idea of the universal object, to limit poverty without hurting wealth, to create vast fields of public and popular activity, to have, like Briareus, a hundred hands to stretch out on all sides to the exhausted and the feeble, to employ the collective power in the great duty of opening workshops for all arms, schools for all aptitudes, and laboratories for all intelligences, to increase wages, to diminish suffering, to proportion enjoyment to effort and gratification to need; in one word, to evolve from the social structure, for the benefit of those who suffer and those who are ignorant, more light and comfort. This is, let sympathetic souls forget it not, the first of fraternal obligations; this is, let selfish hearts know it, the first of political necessities!"

In thanking you for the patience with which you have listen to so long an address, I commend to your consideration the project of the cards for use by practitioners of which I spoke before. By bringing a large number of skilled labourers to the tilling of this field, who knows what good things may be in store for us and our descendants, for remember, "Nature *laughed* when tickled by the hoe."

THE HISTORY OF PROTECTIVE INOCULATION.[1]

By Robert Maguire, M.D. Lond., F.R.C.P.,

Physician to Out-patients, and Joint Lecturer on Pathology, St. Mary's Hospital; Assistant Physician to the Brompton Consumption Hospital.

It has been the custom for one of my colleagues on an occasion like this to address you upon general medical topics. Last year my friend Dr. Waller departed from this custom, and gave you an account of his own brilliant researches upon the "Electromotive Properties of the Human Heart," which have obtained for him the Monthyon prize of the Académie des Sciences of Paris. I would to-day follow Dr. Waller's example in speaking to you upon a subject in my own department; but unlike him, I must offer you only the work of others. The subject of protective inoculation has been occupying the public attention greatly during the last two or three years. I propose to give you this afternoon an account, more or less historical in its arrangement, of the steps by which this discovery has been made, and to show you—as clearly as I can, and I hope, intelligibly to our non-medical friends who are present—the reasonings which have occupied the minds of the observers during their work.

The *rationale* of protective inoculation has been worked out only during the last ten years. Long before this, of course, the fact had been known that it was possible to inoculate persons with the virus of small-pox, so that they might suffer slightly from the disease, and yet be protected from its further action. Such inoculation had been practised in Constantinople as early as the year 1700. Dr. Timoni, a Greek physician living there, wrote of the custom in 1713 to an English colleague, who published his letter in the *Philosophical Transactions*. Inoculation was practically introduced into this country, as you are probably aware, by Lady Mary Wortley Montagu, whose daughter was in 1721 the first person inoculated for small-pox in England. The inoculation was undoubtedly successful in removing the liability to small-pox. It was comparatively free from danger to the person inoculated; but the modified disease was just as powerful as the original disease in spreading small-pox by contagion. Therefore, the practice is now forbidden in England by law. The Gloucestershire farmers had a vague idea that to be infected by the cow-pox relieved man from liability to the small-pox. In 1768 Jenner began to investigate this, and some years later made known that not only was the farmers' notion correct, but that the cow-pox could be indefinitely propagated by inoculation from man to man, and still remain a protection from the more formidable disease. Numerous questions have naturally cropped up in reference to the manner by which the immunity was obtained. It was at one time considered proved that the cow-pox was really the small-pox of man, modified by passage through the cow. Jenner himself, however, thought it was really the grease-pox of the horse. These and other points are still unsettled, and are even now being investigated by a Royal Commission. But in the facts, so far empirically known, we see foreshadowed two important principles, which have attained great prominence in the light of the researches of recent years. These are (1) that by inoculating an animal with a small quantity of virus taken from a mild case at a specific stage of the disease, we may do the animal no immediate harm, and yet protect it from a more virulent poison; and (2) that the same results may be obtained by passing the poison by inoculation from one animal to another of a different species.

Such was the empiric age of protective inoculation. The more scientific investigation of the subject began with a certain disease of fowls, which, I think, is familiar to all who have kept poultry. The disease is now of historic interest, since it was in regard to it that Pasteur first worked out the theory of protective inoculation, which has led him to further and even more brilliant observations. The bird affected by the disease becomes disinclined to move; it mopes by itself in a corner, the feathers become ruffled, the wings droop, the whole body appears to become contracted, so as to look like a fluffy ball; the eyes are closed, or only half open; the bird, when roused, staggers a few feet, with a gait which clearly indicates the great weakness of its muscles, but it soon settles down again into its apathy; at the same time it

[1] An Introductory Address delivered at Saint Mary's Hospital, on October 1st, 1889.

refuses food, and suffers from diarrhœa; very shortly it dies. The disease, which is known as chicken cholera, is prone to attack all the fowls of the yard. Moreover, it is liable to occur in epidemics, and in those districts where poultry keeping is carried on extensively, it causes great loss to the farmers. It had been suspected by M. Moritz, a veterinary surgeon of Alsace, that the affection might be the result of the action of microbes. The germ had actually been discovered by Peroncito, a veterinary surgeon of Turin, and by M. Toussaint, of Toulouse.

But to demonstrate that a disease is caused by a micro-organism, much more is necessary than to merely find a microbe in the tissues of an animal suffering from the disease. The germ must be shown to be constantly present in connection with the disease. Possibly the germ may not always have the same form; many of the microbes known to us occur in two forms, either as the full-grown parasite or as its spore or egg, of which more presently. But one or other form must always be found. It is desirable, too, that only one germ should be found constantly associated with the disease. At the present time we are in a state of uncertainty from this cause in regard to at least two diseases, acute inflammation of the lungs and malarial fever, in both of which several organisms have been found; and we are forced to doubt which is the working cause, or indeed if any one can be so considered. Next, the germ must be isolated from its surroundings. For this purpose it must be grown on what are known as nutrient media, of which there are very many. But all germs will not grow on the same media. Some are intensely fastidious in their tastes. There are, for instance, some known to us which will grow only in solidified human blood-serum, others on that of sheep, and for each germ a suitable medium must be found. It is probable that many germs remain as yet undiscovered, because the proper cultivating substance has not yet been hit upon. Once caught and fastened up—a veritable *Diable Boiteux*—we can do what we like with the minute being. Still, however, we are uncertain of its actual power to do evil. We are surrounded by germs, some of which can be recognised by their forms, others—small as they are—by their chemical reactions; but there are undoubtedly many kinds which are identical in their physical characters. We have, however, a crucial test at our disposal to demonstrate the power or impotence of a given germ to cause disease. In the cultivations upon nutrient media, the germ is in a pure state, and when again introduced into the tissues of an animal ought to reproduce the disease with which it was found associated. This is the crucial test, and without it nothing is certain. The necessary operation is almost, and may be made absolutely, painless to the animal experimented upon. With regard to many diseases this test has now been applied successfully. But it is in relation to this crucial test that many difficulties are experienced. Some kinds of animals are absolutely incapable of being inoculated with the diseases of other kinds. Especially it is noted that the lower animals are never subject to many of the diseases of man. Obviously then, in the case of certain human diseases, the crucial test cannot be applied, and their connection with germs remains a matter of inference, and therefore uncertainty. The reason of an experimenter occasionally runs wild, and he tries his inoculating substances on himself. In the case of some skin diseases, for instance, this may be done without fear of serious consequences; but as a rule it must be considered neither wise nor pleasant to experiment upon one's self.

Pasteur attacked the subject of chicken-cholera with this knowledge of the methods requisite for scientific proof, and found at last, and after some failures, a suitable cultivating medium for this germ. It grew best in a decoction of chicken-flesh. By inoculating portions of such chicken-broth with the blood of a diseased bird, cultivations of the germ were obtained, from which other portions of broth could again be infected. In this way the germ could be sown and bred indefinitely, and collected at last in a state of perfect purity. Then, applying the crucial test, Pasteur injected a small portion of this infected broth into the muscles of a healthy fowl, and by so doing reproduced the original disease in a virulent form, and caused the death of the bird experimented upon. But how to turn this discovery to a useful end was the next question which presented itself to Pasteur. It was clear that the microbe was the cause of the disease; it was proved that it was present in the sweepings of the poultry yard, and spread thus from infected to non-infected fowls. An outbreak might be checked by isolating the fowls, so as to allow all infected birds to die off without coming in contact with healthy ones, and at the same time disinfecting the poultry yard with sulphuric or carbolic acids. Yet all this did not ensure that further outbreaks might not take place, and cause great loss before they could be checked. No means were suggested by which the action of the germs, when once introduced into the body, could be prevented from killing the victim.

These are problems which present themselves in regard to all germ diseases. When once a colony of germs has gained access to the blood, we are powerless to directly control their evil action. The body itself resists their invasion. We have reason to believe that a battle goes on between the blood corpuscles and the germs. As Pasteur has previously shown, there are two kinds of germs—the one requiring free oxygen for their development, which he called aërobies, the other able to live without free oxygen, these called anaërobies. The red corpuscles, which hold the oxygen of the blood, are besieged by the aërobic germs, and defend their store of oxygen against the marauders' attack. If the corpuscles can retain their oxygen, so much the worse for the germs; they must, fighting, die. If the germs are successful, so much the worse, not only for the corpuscles alone, but for the whole body, to which oxygen is as necessary as to the germs. The red corpuscles are mere passive agents in the struggle, but the white corpuscles are active. For the time being they are a defensive army, and resist the invaders with the simple weapon of digestion. They swallow them; but even then the struggle goes on, and while the germ may thus be slain, the valiant defender may have caught a Tartar, who gnaws his vitals and wins the fight. The anaërobic germs also require oxygen, but get it by splitting up the chemical substances of the body which contain it. The tissue cells may resist this by sheer vital powers. Thus, either by actual fighting, or by stubborn tenacity of their possessions, the cells may conquer the germs. Again, the germs, before they have killed the infected animal, may have used up one or other of the substances necessary for their growth and then die of starvation. Further, the germs may actually commit suicide. They are known to produce during their growth certain chemical substances which are fatal to them when they accumulate. In all these ways the body may get the better of the germs, but medicines are in most cases powerless to kill them. We endeavour to keep up the vitality of the cells, but generally the disease runs its course. Disease germs are almost

always surrounding us, and we cannot entirely avoid them. We cannot render all of them incapable of attacking the body, but can we render the body incapable of being attacked by them? To a certain extent we can do this by keeping the bodily functions in a state of general healthy activity, for the greater the vitality the greater the chance of resisting the germs. Yet this does not alone suffice. We find, however, that many of these germ diseases occur but once, or that at least an attack secures immunity from other attacks for a considerable time. It would appear that when the body has withstood the attack of the germs in one of the ways I have mentioned the latter have used up, in their assaults, certain constituents of the body fluids, which are necessary for their life, which are replaced only with difficulty and after a considerable time, and yet are not essential for the vitality of the whole body. Thus, small-pox, scarlet fever, measles, whooping cough, and typhus fever do not usually attack the same person more than once, and the rarity of the exception only proves this rule. If we could be sure of the patient surviving the attack we might inoculate with the original disease at once. But we cannot be sure of the patient surviving the original disease. Yet is it possible to alter the original disease, to change the constitution of the germs, so that they shall be unable to kill the body, but shall yet exhaust the pabulum necessary for their growth to such a degree as to prevent other forms of the same kind laying hold of the system?

I have already alluded to the practice of inoculation for the small-pox, and to Jenner's observation that cow-pox protected from the more serious disorder. We are told that M. Pasteur dwelt long on Jenner's work, pondering on the question whether a vaccine could not be found for other diseases than small-pox. The results of his thinking, and of his experiments upon the germ of chicken-cholera—the way to which was opened up by an accidental observation—were declared to the Académie des Sciences on the 26th of October, 1880. I have mentioned that the virus of chicken-cholera can be cultivated indefinitely in prepared sterilised chicken-broth, by inoculating one portion of sterilised broth from another infected portion, and so on. This is true, provided that too long an interval is not allowed to elapse between the successive inoculations. But if, on the other hand, the broth cultivations of this germ were allowed to remain for some considerable time exposed to the air, but protected from admixture with other germs by a layer of cotton wool, and then other portions of broth were infected from them, Pasteur found that although the form of the germ had undergone scarcely any change, its power of reproducing the disease had been greatly modified. After a certain period, the longer the germ was maintained in contact with the air, the weaker its action became, until at last it had lost entirely its toxic power. Moreover, when cultivations were made from a weakened virus, and continued cultivations carried on, the successive growths retained this modified physiological action. Again, taking a growth which had had its power weakened by exposure to such a degree that it merely made a fowl somewhat ill, and did not kill it, Pasteur found that the fowl experimented upon was now proof against the poison of the chronic form of the disease, which he had previously observed to be by far the most virulent. For chicken-cholera, then, the problem was solved. A vaccine had been found similar to Jenner's vaccine, capable of propagation with retention of its modified powers. It is true that it was not safe to proceed directly from the inoculation of the very weak virus to that of the strongest. Jenner's vaccination is not absolute protection against a strong small-pox poison. It was desirable, then to gradually accustom the fowl to stronger and stronger powers of the virus, until at last the strongest was reached.

How was this modification attained? Pasteur appealed again to experiment, and observed that when his cultivations were protected from air they might be kept for an indefinite time without losing their virulence. It was then, he concluded, the oxygen of the air which caused the attenuation. The first portions of oxygen served for the life of the parasite, for it was an ærobic germ; the further portions weakened its powers. Here, said Pasteur, we may have not only an isolated fact, but a principle, that exposure to oxygen will weaken not only the virus of chicken-cholera, but that of other diseases, that it may be the action of the oxygen of the air which causes the limitation of great epidemics. This may well have been an inspiration of genius, and the inspirations of such a man as Pasteur will extremely probably lead to the truth. But not even a genius can afford to run beyond his facts, and the facts at Pasteur's disposal did not warrant an unqualified acceptance of his theory. It is curious that in even his first paper Pasteur alluded to another view explaining virus attenuation—that there might be an admixture of viruses, the one weak, the other strong, the one counteracting the poisonous but leaving the vaccinating effects of the other. He did not accept this view, but in mentioning it he foreshadowed an objection which has been raised, in regard not only to the attenuation of fowl-cholera, but to that of other diseases on which he has worked. Other observers have found that his vaccine fluids have not been pure, that other forms of micro-organisms had become mixed with the original poison. Now, there is a sort of internecine war amongst these low organisms; they fight amongst themselves as to which shall take the opportunity to do evil. It is suggested that the reason why the virus becomes attenuated is that there has gone on a growth of an entirely different microbe, which has modified the action of the first. Pasteur denies this, but it is to be noted that he did not employ the fine methods of detecting and differentiating germs which have been worked out by the German scientist Koch. Be this as it may, Pasteur used his theory of the attenuation of virus by the action of oxygen as a working hypothesis, and immediately proceeded to test its applicability to other germs.

Chicken-cholera was a comparatively small matter, as regards the loss to the farmers which it entailed. Another greater trouble attacks cattle, sheep, and horses, and is widely spread over many countries. It is known variously as the splenic fever, charbon, milzbrand, black-quarter, the Siberian pest, the murrain, and it is even communicated to human beings, causing the so-called malignant pustule of the dock labourers, who handle infected hides, and the Bradford wool-sorter's disease. This also is a germ disease, and its micro-organism was discovered in 1849 by Pollender, and independently by Brauell. Its connection with the disease was shown by Davaine in 1863, but the life-history of the parasite was worked out by Koch, and published in one of his earliest papers. In 1881, the devastations of the disease were in France much less than they had been, for, in fear of the pestilence, farmers had greatly diminished their flocks; nevertheless, the losses were very great. There is a district of France lying between Chartres and Orléans, which is extraordinarily fertile, and is known as La Beauce.

In this district, in 1842, one fifth of the sheep died annually from this disease, and in 1881, one tenth. In 1842 the loss to the farmers was estimated at seven million francs a year, and in 1881 at three million francs. Pasteur then directed his attention to the possibility of procuring a harmless vaccine for the disorder, using as his guide the theory of attenuation by oxygen, which he believed to have been indicated by his experiments on chicken-cholera. But the attenuated virus can only be protective when the disease occurs but once in the same subject. Hitherto this was unknown, but accidentally Pasteur and his assistant Chamberland found several cows which, after inoculation with the poison, and after suffering severely, at last recovered. The same cows when re-inoculated, even after an interval of a year, were unaffected by the poison.

Thus, then, the disease presented a fair field for the application of Pasteur's new theory. He appealed again to experiment, attempting, by exposing his cultivations of the germ to the air, with due precautions, to attenuate the virus—but he failed. This, however, was only a further stimulus to Pasteur to ascertain the cause of the failure. Indeed, I think we may accept it as an excellent guide to experiment, that the failure of a preconceived notion means that a new fact is presenting itself for observation, something that we did not know before, or which we thought was incapable of interfering with the experiment. Pasteur soon found the cause of his failure. The germ of chicken-cholera has only one form, and reproduces itself by division and multiplication of the elements, the new parts of the germ having exactly the same properties as the parent germ. The germ of splenic fever, the anthrax bacillus by name, grows in the same way at times, but it has also another method of reproduction. In the centre of each of the rods representing the germ there forms a round or oval body, behaving very differently in its chemical reactions to colour-reagents than is the habit of the parent rod. This round or oval body is the spore or egg of the germ. It becomes in time separate from the rod, and afterwards develops into a rod, and possibly into a series of rods, which under suitable conditions, again develop spores. The germ then has a dual existence, as rod and as spore. But the vitality of the two forms is very different. The rod can be comparatively easily destroyed, but the spore may remain dry, exposed to the air and starving, as it were, for years, and yet retain its power of reproducing the virulent disease. The method of attenuation which Pasteur had made use of in the case of chicken-cholera, would clearly be useless in dealing with the anthrax bacillus so long as the power of generating spores remained. Pasteur then had this problem before him: How to grow the anthrax bacillus without spores? This he soon solved. The anthrax bacillus grows only within certain well-defined limits of temperature, namely, 16°C. to 45°C., and below the one or above the other temperature no reproduction whatever can take place. Moreover, Pasteur observed, that as the limits of vitality were nearly reached, the germ reproduced itself only as rods; it had lost the power of forming spores. In this state Pasteur's formerly successful method of attenuation could be again tested. He did so test it, and discovered that when the germ was grown at a temperature between 42° and 43°C., and exposed to the air for eight days, all virulence was lost. Before this stage was reached, just as in chicken-cholera, grades of attenuation were observed, which could be reproduced by cultivation, and retain their modified powers. An animal might be inoculated with a weak virus, be made slightly ill, and recover. Then it was proof against a stronger virus, and after that the most powerful virus produced no effect. Thus again did Pasteur attain a great result, which seemed likely to benefit hugely his fellow creatures. But all this was mere laboratory work, and how often do we see that chemical methods, apparently admirable in the test tube and microscope stage, fail utterly when applied to practical every-day use? Pasteur, however, had faith in his results. He challenged the most searching test, and this was applied at Pouilly-le-Fort in May, 1881. On May 5th, twenty-four sheep, one goat, and six cows were inoculated with an attenuated virus of anthrax. On May 17th all these animals were inoculated with a somewhat stronger and yet an attenuated virus. On May 31st the animals were inoculated with the strongest virus, and at the same time an identical poison was injected into twenty-four sheep, one goat, and four cows, who had not been previously vaccinated. A meeting was arranged for two days later (June 2nd) in order that the result might be observed.

It is desirable that sensation should be entirely eliminated from all scientific procedures. Yet for this afternoon we are not severely scientific, and I may be allowed to quote the graphic account of the result given by M. Radot, the son-in-law of M. Pasteur, whose book on the life and labours of Pasteur has been admirably rendered into English by Lady Claude Hamilton.

"More than two hundred persons met that day at Melun. The Prefect of Seine-et-Marne, M. Patinot, senators, general counsellors, journalists, a great number of doctors, veterinary surgeons, and farmers; those who believed and those who doubted came impatient for the result. On their arrival at the farm of Pouilly-le-Fort they could not repress a shout of admiration. Out of the twenty-four sheep which had not been vaccinated, twenty-one were dead; the goat was also dead; two other sheep were dying, and the last—already smitten—was certain to die that very evening. The non-vaccinated cows had all voluminous swellings at the point of inoculation, behind the shoulder. The fever was intense, and they had no longer strength to eat. The vaccinated sheep were in full health and gaiety. The vaccinated cows showed no tumours; they had not even suffered an elevation of temperature, and they continued to eat quietly."

"There was a burst of enthusiasm at these truly marvellous results. The veterinary surgeons especially, who had received with entire incredulity the anticipations recorded in the programme of the experiments, who in their conversations and in their journals had declared very loudly that it was difficult to believe in the possibility of preparing a vaccine capable of triumphing over such deadly diseases as fowl cholera and splenic fever, could not recover from their surprise. They examined the dead; they felt the living.

"Well," said M. Bouley to one of them, "are you convinced? There remains nothing for you to do but to bow before the master," he added, pointing to Pasteur, "and to exclaim: 'I see; I know; I believe; I am undeceived.'"

"Having suddenly become fervent apostles of the new doctrine, the veterinary surgeons went about proclaiming everywhere what they had seen. One of those who had been the most sceptical carried his proselytising zeal to such a point that he wished to inoculate himself. He did so with the two first vaccines, without other accident than a slight fever. It required all the efforts of his family to prevent him from inoculating himself with the most virulent virus."

Pasteur's researches were, as was to be expected, immediately subjected to searching criticism. It was asserted that the method of vaccination was dangerous to the animals upon which it was practised. To a certain extent this was true, for the attenuation of the virus was not always uniform. This Pasteur recognised, but thought that all risks would be covered by a small guarantee fund. Again, it was said, and said truly, that the immunity obtained against the disease was not everlasting. Neither is that of Jenner's vaccine. The duration of immunity obtained by Pasteur's inoculation was proved to at least exceed a year, or one third the ordinary life of a sheep, and then the inoculation might safely be again performed. It was maintained that the immunity was only against the injected virus, not against that spontaneously absorbed by animals through the medium of their food. But what did the results show after time had elapsed for a sufficient accumulation of facts? Among 32,550 sheep inoculated the mortality from anthrax was 1 in 740; among 25,160 not inoculated the mortality from anthrax was 1 in 78; and similar results were obtained from the inoculation of horned cattle. The most serious criticism of Pasteur's results came from Dr. Koch, yet on careful reading of his paper it seems to me to deal greatly with mere minor matters, and in its final passage admits the main point that Pasteur had given full and complete proof that artificial immunity could be obtained. Dr. Koch and his colleagues indeed lent precision to Pasteur's method by indicating the exact temperature, 42.6° C., at which the attenuation could be best conducted. Further researches by various observers led to the discovery of other methods of attenuating virus. Toussaint had previously shown that by heating the bacillus anthracis to 55° C. for ten minutes, its virulent action was destroyed, and yet it rendered the animal inoculated with it safe against the ordinary poison. Pasteur showed that this was true, but that the attenuation was transient, and was also uncertain, and therefore the method unsafe. Again, Chauveau found that to heat the organism to 47° C. for a certain time, attenuated its powers, and that the result could be obtained more rapidly in this manner than in that invented by Pasteur. He showed again that similar changes could be produced by keeping the germ at a temperature of 38°-39°C. under a pressure of eight atmospheres. Chamberland and Roux also tested the action of antiseptic substances upon the germ, and arrived at this: that carbolic acid, and other substances of similar germicidal properties, could attenuate the virus. The germ kept for twenty-nine days in a broth containing $\frac{1}{600}$ carbolic acid does not kill guinea-pigs or rabbits, but protects them from the action of stronger poisons.

Most curious results, too, have been obtained by inoculating the poison of one animal into another of a different species. Toussaint found that the germs of septicæmia in the rabbit closely resemble, even if they are not identical with, those of chicken-cholera. He arrived at the startling result that if fowls were inoculated with the blood of rabbits dead of septicæmia, they were proof against further attacks of chicken-cholera. Thus by passing through an animal of a different species, the germ lost its virulent, but retained its vaccinating, properties. Later on, Pasteur and Thuillier experimented upon the organism of swine-plague. The poison of this disease—a germ resembling those already mentioned—was poisonous to pigeons; and when inoculated from pigeon to pigeon, its virulence increased, not only in regard to the pigeon, but also to pigs. The same poison killed rabbits, and inoculation from rabbit to rabbit increased the virulence as regards the rabbit. But the virulent poison of the last rabbits of a series is much less virulent to pigs than it was at first. It ceases to kill them, but protects them from all further attacks. In a still later series of experiments Pasteur discovered that a similar germ—that of sputum-septicæmia, which was at first mistaken for that of hydrophobia—rapidly killed rabbits, but was innocuous to adult guinea-pigs. Yet it could kill very young guinea-pigs, and if the germ were from them conveyed to older and still older guinea-pigs, it became excessively virulent, and killed them also. But now, after passing through the guinea-pig, the poison had entirely lost its power of infecting rabbits, but still protected them from further attacks. Later in his work, as will be related below, Pasteur found that the hydrophobic poison was similarly attenuated by passage through monkeys. After considering these facts, one is driven again to ask, as was asked, and, indeed, investigated in vain years ago, whether Jenner's vaccine is not an example of a similar attenuation?

Another disease succumbed to protective inoculation. Chabert's disease, as it is called, was confounded for a time with anthrax. It is characterised by high fever, and widely spread inflammation of the connective tissue; it occurs in young cattle and lambs. Its poison can be attenuated, and will then after inoculation confer immunity. It is interesting to note also that if a small quantity of the fresh virus be injected into the loose connective tissue of any part of the body, slight indisposition follows, but absolute further immunity results—a counterpart of the ancient practice of inoculating for the small-pox.

But have these diseases become essentially changed during these various modifications? Are they entirely different disorders, incapable of ever reproducing the virulent diseases from which they originated? Another question, this, which Pasteur solved, The poison which no longer kills a fowl with chicken-cholera, would still kill a small bird, such as a canary, and by successive cultures through larger birds could at last regain all its old virulence. The poison which no longer killed a sheep with anthrax could kill a guinea-pig one day old, and again by successive inoculations would regain its old power over the sheep. Pasteur had formerly suggested that exposure to the action of oxygen might be the explanation of why epidemics of infectious diseases declined. Have we not here, said he, in the facts of re-installation of virus an explanation of why infectious diseases have apparently originated *de novo*, and why epidemics of formerly known diseases recur. The poison has for ages been too weak to attack a bulky animal like man, but it has become gradually enforced by passing through the bodies of smaller animals, and so new virulences and contagions have been formed.

The natural immunity of some animals from certain infections gave rise to an interesting experiment, which, though somewhat out of place, may be related here. Fowls are absolutely incapable, in the natural state, of being inoculated with the anthrax germ. Why is this? The temperature at which the anthrax bacillus ceases to grow is about 44°C., as I have already stated. The temperature of a fowl is between 41° and 42°C. In a simple fluid the bacillus would easily, even at this temperature, assume the oxygen requisite for its growth. Pasteur thought, however, that in the blood matters might be different. The red corpuscles

would cling to their oxygen, and their tenacity might more than compensate for the 3° of temperature which separated that of the blood from the life limit of the bacillus. But if the blood of the fowl were cooled the struggle would be less equal, and the increased vitality of the germ would overcome the grasp of the corpuscles on the oxygen. He made the experiment. A hen was inoculated with splenic fever blood, and by placing its feet in cold water its body temperature was lowered to 37° or 38°. In twenty-four hours it was dead of anthrax. Moreover, if the hen, before its death, were taken out of the cold water, wrapped in wool, and kept at a temperature of 35°, its body temperature again rose, its strength returned, and in a few hours it was well. The fight between the corpuscles and the bacilli had been won by the former, and the latter disappeared.

Pasteur's inspiration, that oxygen was the active agent in inducing the attenuation, had been much attacked. Chauveau, for instance, found that when germs were heated to 47°C. attenuation was more rapid when the air was exhausted. Apparently it was the heat which was the active agent. Nevertheless, Pasteur still used his theory as a working hypothesis, and we shall now see what is, for the present, the final and most brilliant result of his researches.

In the diseases previously mentioned a definite germ had been found, and the connection of the germ with the disease abundantly proven before any attempt had been made to attenuate the poison. Yet there are many diseases of which the course of the symptoms and the methods of occurrence create a strong suspicion—almost a certainty—that they are germ diseases, and yet so far no germ has been discovered in relation to them. Of these, perhaps the most terrible is hydrophobia. In man, at least, it is absolutely incurable ; it causes the most painful of deaths, and the fear of the outbreak haunts the victim for a considerable time before the actual symptoms begin. Pasteur and others had hunted diligently for the germ of this disease, but without success. Whatever the germ may be it is something entirely different in form and physical characters to any already known. It has been suggested that curious granular bodies seen in the nervous system of rabid animals may be the actual poison, but this is not yet proven. Baffled in his search for the germ by its strange physical characters, Pasteur nevertheless tested whether its physiological characters might not be the same as those already known. To do this it was necessary to obtain the poison in as nearly as possible a state of purity. Since the method of cultivating the germ was not applicable, other means had to be found to free it from—at any rate—the germs of other diseases.

M. Radot again gives a most graphic account of how Pasteur obtained poison from the saliva of a rabid dog. "Not long ago," he writes, "a veterinary surgeon telegraphed to him : 'Attack at its height in poodle-dog and bull-dog. Come!' Pasteur invited me to accompany him, and we started, carrying six rabbits with us in a basket. The two dogs were rabid to the last degree. The bull-dog especially —an enormous creature—howled and foamed in its cage. A bar of iron was held out to him : he threw himself upon it, and there was great difficulty in drawing it away from his bloody fangs. One of the rabbits was then brought near to the cage, and its drooping ear was allowed to pass through the bars. But notwithstanding this provocation, the dog flung himself down at the bottom of his cage, and refused to bite. Two youths then threw a cord with a slip-loop over the dog, as a lasso is thrown. The animal was caught, and drawn to the edge of the cage. There they managed to get hold of him, and to secure his jaws ; and the dog, suffocating with fury, his eyes bloodshot, and his body convulsed with a violent spasm, was extended upon a table and held motionless, while Pasteur, leaning over his foaming head, at the distance of a finger's length, sucked up into a narrow tube some drops of the saliva. In the basement of the veterinary surgeon's house, witnessing this formidable *tête-à-tête*, I thought Pasteur grander than I had ever thought him before."

The poison then was present in the saliva of a rabid dog, but with it was the germ of sputum-septicæmia, which I have already mentioned. A most virulent poison was, however, found in the nervous system of an animal dead of rabies, and when due precautions were taken in removing the spinal cord, the poison therein contained was absolutely free from foreign microbes. An emulsion of such a cord would reproduce hydrophobia, in all probability if injected into the circulation of another animal, with absolute certainty if, by the operation of trephining, it were placed in direct contact with the brain. Pasteur accidentally met with a dog which had recovered from inoculated rabies, and this animal was found to be proof against further poison, even when applied by means of trephining. He was, therefore, encouraged in his attempts to obtain a vaccinating fluid for the disease. Rabbits, guinea-pigs, fowls, and monkeys were experimented upon, and it was found possible to inoculate all these with the fatal disease. Further, from such inoculated animals the disease could be re-transferred to dogs, but not absolutely in an unchanged state. In passing from dog to rabbit, and then from rabbit to rabbit, and so on in series, the poison increased greatly in virulence. The first rabbit inoculated would present symptoms after a period of about fifteen days. After passing through forty-six rabbits the incubation period was almost constantly seven days, and the poison would then cause rabies in dogs after an incubation of from eight to ten days. In guinea-pigs similar results appeared. But when the virus was passed from dogs to monkeys, and afterwards from monkey to monkey, it became feebler at each passage. After passing through several monkeys, a poison is obtained which, when inoculated in the dog by trephining, in most cases caused no symptoms of hydrophobia, but protected the animal from a stronger poison. In this way a series of poisons could be obtained, extending from the innocuous monkey virus to the most virulent rabbit poison, and the weakest of these protected from the next in series, and so on.

This method, however, was not absolutely certain in its results, and, moreover, was slow in process. The poison of a rabid dog, inoculated into a human being by a bite, remains dormant for a certain time—on the average six or seven weeks. An uncertain interval will probably elapse before the patient comes under treatment, and what is desired for practical purposes is that between the bite and the onset of symptoms an inoculating fluid should run through the whole of its course so as to produce immunity before the strong poison is completely incubated. In England we believe that Jenner's vaccine can so outpace the small-pox poison. The hydrophobic poison, attenuated as I have described, is not sufficiently rapid in its work. Now came in Pasteur's working hypothesis. He had obtained an excessively-strong poison of constant virulence. Possibly it could be attenuated by exposure to the air, like the other poisons he had worked with ; therefore he suspended spinal cords from infected

rabbits in jars, the air in which was rendered aseptic and dry. Thus the goal was reached. The rabic effects of injecting portions of such spinal cords into dogs decreased in power the longer the cords were so kept.

A portion of cord thus treated for fourteen days would not kill a dog, and after its injection, that of sixteen days ceased to kill. Thus proceeding from weaker to stronger cords, at last the most virulent cord—containing poison much stronger than that of a mad dog's saliva—can be injected with impunity, and total immunity is reached. The whole course of such treatment can be completed in sixteen days at most, as a rule before the poison inoculated by an ordinary bite can have incubated. But bites inflicted on the face, and those by wolves, have a shorter period of incubation than those on other parts of the body, or inflicted by dogs. For these cases an intensive treatment was conceived, into the details of which I need not enter. Its course could be completed in seven days, but as a further safeguard, it is repeated in a modified form once or twice. The interpretation of this method of attenuating virus has also occupied Pasteur's mind, but as yet no definite conclusions have been arrived at. He thought that the extension of the incubation period observed in the long-exposed spinal cords pointed to the fact that not the strength, but the quantity of the virus contained in the cords progressively diminished. Pasteur, and also Bardach, have shown by experiment that the strongest poison taken in a recent state from a rabbit may be with impunity injected into a dog, if only a small quantity be used, and afterwards larger and larger quantities may be injected until absolute immunity is attained. Yet this method is uncertain in its results. The theory which at present attains the greatest favour with Pasteur is that of bacterial suicide, to to which I have already incidentally alluded. It has been ascertained that bacteria in the course of their growth produce certain chemical substances, which inhibit their action. Possibly, when the virus is apparently attenuated, the quantity of the germ is diminished, but that of the counteracting fluid produced by it is increased, and so no ill results follow. At present, the facts observed in support of this view are few, but the question is being diligently worked at by experimenters.[1] The details of treatment do not concern the subject of my address. The results of the treatment required time and experience for their due appreciation. Now, they may be judged with confidence. The statistics have within the last few days been most carefully arranged and published by Dr. Ruffer. In short, they may be stated thus. All doubtful bites are rejected, and every precaution taken against error. The lowest possible mortality which can be calculated of patients who were bitten by rabid animals, and not treated, is 15 per cent., and probably this is much *under* the mark. The highest possible mortality which can be calculated of patients who were bitten by undoubtedly rabid animals, and were then subjected to Pasteur's treatment, is for the year 1887 1.52 per cent, for 1888 1.31 per cent., and probably this is much *over* the mark. Such numbers place beyond doubt the value of Pasteur's discovery, and render it desirable that his treatment should be within the reach of all. This then is for the present the practical limit of these researches, but we are still only on the threshold of the discoveries which may be made by the application of these methods.

An introductory address, like a fable, should carry a moral; and mine, as being somewhat longer than an ordinary fable, may be permitted to have two morals. There was a time when it was difficult to persuade students, and even practitioners of medicine, that it was necessary to know physiology before one could learn medicine. Those days have gone: it is now accepted by all that the man who has the most competent knowledge of physiology is in the best position to become a successful practical physician. It would seem that if the science of the normal body were necessary, *à fortiori* that of diseased states was doubly so; and yet, such experience as I have had as a teacher leads me to say that even now students by no means appreciate the intimate connection between pathological science and practical medicine. The researches I have endeavoured to put before you were in the domain of pure and even obscure science, yet they have led, as you see, to the most important practical results. We cannot all hope to make such discoveries. But let me impress upon you also that it is its scientific basis which gives to the art of medicine extreme interest to its practitioner, which renders it so much more absorbing than any other of the learned professions. There will come to you all in after life a period in which the public is little inclined to trust your skill, and just as little disposed to pay you for your labours. Moreover, when the reward does come, if prognostics may be trusted, it will be scarcely commensurate with the toil expended for it. To all these are trials. To him who has learnt his profession by rule of thumb there is but little solace, and all his future work must be labour, and nought else. On the other hand, to him who knows what a great field of observation is open to him, and whose studies have fitted him to appreciate the great wonders which surround him, there is another reward than that of mere worldly gain: as one of our own physicians once put it to me—"One's work is a great comfort." My first moral, then, is, that you should on no account neglect the scientific aspects of your studies, in that they will render you the better practitioners, and console you in your many troubles.

My second moral is, that you should always be working, and be not disheartened by difficulties. I would enforce this precept by the examples of two men—Pasteur and Koch—whose names I have mentioned this afternoon. M. Pasteur was trained as a chemist, and by education knew nothing of Medicine. Led by his researches upon the tartrates and the para-tartrates to an investigation of those living ferments which played a part in the chemistry of these salts, he applied his great observant powers to an elucidation of the life of the infinitely little. Gradually he unfolded the science of vinegar formation, and of the causes for wine going wrong. He was then induced by his master, Dumas, to investigate the silk-worm diseases, which were at that time ruining the industry of the south of France. The results of his observations have, it is said, saved to the French more than the milliards taken from them by the Germans. In 1868 he was smitten by paralysis of one side of his body, from which he has not completely recovered. This would be for most men a sufficient excuse to cease work; but Pasteur sought only excuses to continue work, and disabled as he was, he journeyed to Saint Hyppolyte du Fort, and afterwards to Trieste; and there, reclining in an arm chair,

[1] In a recent number of the *Brit. Med. Jour.*, Oct. 12th, 1889, p. 810, Mr. E. H. Hankin has published a preliminary notice of experiments, which shew that for the anthrax bacillus the substance which protects an animal against its action is an albumose, produced by the bacillus. It would appear that it is by means of this albumose that the bacilli overcome the germicidal power of the animal. Yet by injection of small doses of such albumose, tolerance is established, and finally immunity from the action of the germ itself.

directed experiments confirming his previous observations on the pébrine and flâcherie of the silk-worm. Still working, he studied the diseases of beer, and afterwards devoted himself—and is even at the present time devoting himself—to the subjects of which I have given you a sketch to-day. Dr. Koch was an obscure country practitioner in Germany, and whatever may be the hardships of country doctors in England, in Germany their condition is far worse. Yet he worked at something more than the mere routine of his profession, and in his country surgery with but the simplest appliances, pursued those observations upon septic disorders which have made his name famous. As Director of the Hygienic Institute of Berlin, he also continues working, and has founded a great school of scientists, whose labours upon the subjects of tuberculosis, cholera, diphtheria, and disinfection, have benefited their profession and honoured their country. May we follow the examples of these two men, and all of us, even in a humble way, endeavour to leave the world somewhat better than we found it.[2]

Special Articles.

THE WORKING CLASSES.

On August 1st, 1874, the centenary of Joseph Priestley's discovery of what he called dephlogisticated air, but which French chemists subsequently named oxygen, a statue of the great chemist was presented to the town of Birmingham, and Professor Huxley delivered a characteristic and eloquent address—subsequently published, with many additions, in *Macmillan's Magazine* for October, 1874. Mr. Huxley's address has been so widely and attentively read, and in so many forms reprinted, that its substance must be familiar to my readers. Although not near enough to catch Huxley's words, I was close to him at the public ceremony, and can recall the pleasant excitement in the town at the time, and the almost unanimous feeling that England, but more particularly Birmingham, was advancing by leaps and bounds, socially, morally, and politically, and my readers will not forget that we were then in the midst of a golden commercial age. Knowing what Birmingham did of Huxley's broad and unconventional views on social, religious, and scientific questions, it was expected that he would pay a generous tribute to the labours and achievements of the great chemist, whom an ungrateful country banished to the United States. Still more surprising would it have been had he not spoken with warm, though qualified, approval of the religious opinions of a man who was theologian and politician, as well as chemist and discoverer. Huxley reminded his hearers that Priestley believed in the possibility, rather than in the certainty, of human perfection; and though Huxley hesitated to say so positively, he evidently expected continuous progress, and thought that in morals, science, religion, and politics, great advance had been made since Priestley was persecuted by his fellow-townsmen. No one can deny that from the hour of Priestley's birth to that of his death, improvement in the arts and sciences was continuous, and during the whole time that has since elapsed, there has been change, and not only material, but, let us fervently hope, moral progress. I confess, nevertheless, that I hesitate to accept the eager hopes of many excellent Unitarians as more than brilliant visions of what might be—visions inspired by that devotion to progress and love of freedom for which many of Priestley's co-religionists have always been conspicuous. Nor am I sure that there is sufficiently solid foundation for the promises of continuous social amelioration which scientific men hold out. From my earliest childhood I have felt the deepest interest in the working-classes—their patient, uncomplaining heroism, their thriftiness, their great temptations. Often, when a little boy, I used to pass hours at a time in the grimy workshops of Staffordshire nailers, listening to their simple talk, and perhaps being more deeply impressed by the wisdom of their political opinions than now (looking back a quarter of a century) seems possible. How easily those unsophisticated farm labourers and hammer makers would have cut the knot of great social difficulties; how direct their remedies for existing anomalies. The ways of children please the child; and working-men are often little more than children of larger growth, and trouble themselves not at all with any deep scrutiny into human motives, and the complex problems of modern society, with its mutual checks and conflicting interests.

In spite of revelations regarding the sweating system—not by any means novel, as Alton Locke must remind my readers—in spite of the suffering of the unemployed, both of those who cannot and of those who will not get work, in spite of Bitter Cries, advance there has been, and advance is going on all around us. We may not think ourselves in Paradise, and yet we must admit this. Things must have been incomparably worse a few generations ago than anything we see about us to-day. If anyone doubts the reality of modern improvement, let him take up Macaulay; and without necessarily endorsing every word, he will wonder how, if what that great historian says is true, the working-classes kept body and soul together a few centuries ago: so deep was their degradation, so brutal and sensual the character of their masters. Turn where we will to the writings of historians and sociologists, we are told of improvement, discovery, increased wealth everywhere; and if we read any magazine or review, not pledged to uphold the familiar and time-honoured, the same picture meets us of rapid progress and constant amelioration in the condition of nations and classes: this I cannot deny, and I am indeed thankful for it. But when, turning from the records of Roman feasts and gladiatorial combats, from narratives of the intolerance and persecution of the Middle Age, from eulogiums of the present, I wander—according to the custom of many years, dating, indeed, from the ripe age of eight—through the squalid haunts where vice, intemperance, disease, and irreligion hold their hideous revels. When I compare the numbers and habits of those degraded millions, whom we scornfully call the masses, with the condition of the small minority forming the dominant classes, I am constrained to admit that the misery in this favoured and prosperous land is still appalling in amount and intensity. I do not blame anyone for it, and I no longer expect much from legislation: the people must be radically improved, bodily raised, and that can only come from a change in their morals and manners, which must necessarily be slow. But it is not the outcasts alone whose condition calls for regret—worse still, some knowledge of the manners of the privileged few makes me doubt whether, as a class, they deserve special respect and homage. Their vices and shortcomings are, in their way, as strongly marked as those of their inferiors; and though

[2] In compiling the above address, the original papers were referred to as far as possible. The writer, however, wishes to acknowledge the assistance he received from M. Radot's "Life of Louis Pasteur," translated into English by Lady Claude Hamilton; and from the admirable collection of translations and abstracts on "Attenuation of Virus," by Dr. Dawson Williams, published by the Sydenham Society.

less repulsive to the superficial inquirer, their moral turpitude often leaves little to choose: in short, nowhere are purity and contentment the distinguishing characteristics of a class.

When, my confidence in the excellence of the present shaken by observation and reflection, I take up the works of men who, whatever their religious or political opinions, are not blind admirers of the present, what do I find? When I study Froude's pictures of the almost forgotten pre-Reformation days, and Charles Kingsley's panegyrics on the manliness and heroism of the sailors and statesmen of the Elizabethan age—and surely Froude and Kingsley stand in the van of liberal and fearless thinkers—I must admit that the advantages of the present may not be above dispute; and that, though modern changes are undoubtedly vast, there is no saying how much of those changes have been improvement, nor how many of our reforms are for the better. And my suspicion acquires strength that many schemes for the regeneration of this nation, and indirectly of the world, are sometimes only attempts to undo the evils of recent changes of manners and habits, when I find eminent writers pointing with indignant horror to cankers in our social system, which, from the very nature of the case, can only be of modern growth. Take, for example, Mrs. Beecher Stowe's comparison, in "Uncle Tom's Cabin," of the condition of English mechanics and farm labourers with that of negroes in Carolina and Louisiana. Mrs. Stowe probably obtained her information respecting our countrymen from the periodicals and newspapers which came in her way during her stay among us, and what she read did not prepossess her favourably. True, Lord Carlisle emphatically denied the fidelity of her comparisons; and Sir Arthur Helps, one of the kindest and best of men, in a paper in "Fraser," over thirty-seven years ago, attempted to disprove the accuracy of her strictures, as far as concerned our working classes. But the fact remains that foreigners, from what they have read and heard, are not always convinced of the immunity of English artisans from the miseries that undoubtedly darken the lot of foreign labourers, but which some of us venture to hope do not invade our happier shores. Mrs. Stowe's strictures have been repeated by many continental writers, in some cases from their own knowledge, in others relying on what some of our countrymen have divulged. And, again and again, as a sorrowful refrain to the descriptions which enthusiastic writers and orators give of the prosperous condition of our countrymen, we hear accounts of such misery and temptation, such grinding poverty, such living death, such a struggle for the bare necessaries of existence, that we wonder who is right, who wrong; but for the credit of our common humanity hope that exaggeration and falsehood underlie some of the terrible tales that, from time to time, force themselves upon our notice, and almost make us despair of our species.

Marvellous progress is being made in every department of science and art, and the appearance of the country is in consequence being totally changed. What were a few years ago the luxuries of the rich, are now the possession of the poorest, and never in modern times has money gone farther. Year by year, and as the result of the utilisation by practical men of the crude suggestions of the very unpractical men, who devote their lives to original research, and fancy, when they have got an inkling of something new, they have done all that could be expected, there is rapid increase in the national wealth, and, at the same time, vast schemes for the amelioration of our countrymen are yearly broached. For whose benefit is modern legislation in the main—for that of the poor—the extension of the franchise, board schools, county councils, third class fares, cheap books, the enlargement of hospitals, and much else, are far more for the poor than for the middle and upper classes. But it is unfortunate that the progress of the arts, good in itself, is not everything, and the greater cheapness of the luxuries of civilised life is not productive of all the good contemplated. There is increasingly greater profusion, but man's wants increase *pari passu* with the development of commerce. The savage wrapped in his tattered blanket is not so often a sufferer from cold as the English merchant who draws round his shivering limbs three coats, and a mountain of linen, flannels, and other garments. The children who, in every Irish town, run barefoot across the streets, suffer less from cold, and far less from corns, than their social superiors who squeeze their feet into tight and uncomfortable boots. The artificial life of our age is not everything, though undoubtedly in some respect an improvement on a simpler existence. The perplexed merchant, broken down by worry—that bane, as Sir Arthur Helps so felicitously called it, of modern life—is not always happier than the humble village carpenter or blacksmith, the oracle of an admiring circle: as much contentment may be found in a lowly cottage as in a stately mansion. Mere increase of wealth does not necessarily mean greater general prosperity, or a higher average of that peace of mind and sense of duty, the true standard by which to measure national progress.

Sometimes we forget that the conditions of modern life bring with them evils which it taxes our resources to the uttermost to control. The vaunted superfluity and luxury of our day are attended by diseases and miseries worse than those of simpler ages and races. Let it not be thought that I am a *laudator temporis acti*, and that my knowledge of the past and the present is so imperfect and one-sided that I fancy that any age or country ever was or ever will be free from care and sorrow. Never has there been, and, unless human nature totally changes, never will there be, a golden age. I am convinced that, on the whole, the condition of England is vastly better than formerly, though there remains great need of improvement; and with my tastes and opinions, life in England is pleasanter than life anywhere else. Yet can I easily perceive why, for example, James Fenimore Cooper should have preferred the freer institutions of his native land to those of England, and why many Italians and Germans should see more to admire in their respective countries than in England or America. The feeling of despondency that fills me when I read Walter Bagehot's lament that "it is dubious whether all the machines and inventions of mankind have yet lightened the day's labour of a human being" (and remember that what I have seen confirms his gloomy doubt), is more than I can express.

For one side of a most difficult question—the present condition of the labouring classes—take up a report published a few years ago by Mr. Brewer, one of the sub-inspectors of factories of that English desert, the Black Country, and what do you find? What do you find in the reports which many other inspectors have year by year laid before the nation?—sensuality, vice, lawlessness, misery, grief, that seem without a redeeming feature: men whose only pleasures are dog fighting, the prize-ring, the public-house, and sensual indulgence; women so lost to decency and good feeling, that they are indifferent to the brutal sports of their husbands, and sometimes actually take part

in them; children diseased, miserable, and neglected, in many cases born only to die: this is the drift of those repulsive narratives. I have myself seen, more than once or twice, a gathering of two thousand and over of the lowest sporting men of Birmingham engaged in rabbit coursing or pigeon shooting, which are among the chief amusements of certain classes of the midland metropolis, and I will not deny that a more frightful assemblage of unmitigated blackguardism I never wish to see. I cannot advise parents to let their sons study the real habits and language of the working classes amid the conditions in which I have investigated them. No harm came to me, however. I went alone, a curious observer of human manners and customs, and could not have been much more than eleven when I first found myself in such places. Fortunately, the opportunities I then enjoyed have been invaluable, and have given me an insight into the humbler classes that few professional men acquire, except occasionally doctors, whose knowledge of their poorer brethren would often shame that of the clergy. Let all this be conceded; still, thank Heaven! this vile residuum does not represent the masses of the nation.

Turn to the indignant defence of the South Staffordshire nailers, which the late Rev. R. Hone, one of the kindest and ablest of the Black Country clergy, published in reply to Mr. Brewer's report, and you find that the Venerable Archdeacon, whom in my childhood I knew intimately, and to whose virtues I can testify, qualified those dark statements. Mr. Hone did not altogether deny them, but from his knowledge of Halesowen, where he long and zealously laboured, he was sure that qualifications were necessary. Both Mr. Brewer and Archdeacon Hone were, it may be, perfectly right. Among the Black Country operatives, sensuality, drunkenness, and lawlessness abound to a degree enough to appal men of strong nerves—that is the black side. But, as Mr. Hone also knew and said, there were many redeeming traits. The miserable, squalid home, to those accustomed to it, is not necessarily uncomfortable. The rough language of colliers and nailers, intolerably offensive to persons of refinement, is not repulsive and disgusting to those who understand it, and can make proper allowance for it. Nay, the very sports, so brutal in themselves, so degrading as they seem to us, do not always show unqualified wickedness. How some of my collier friends loved their bull-dogs; they would have gone without their own dinner rather than let their favourites want a meal. How kind and tender some of those rough, coarse fellows are at heart! Without wishing to hold up for commendation, much less for imitation, the lives, homes, and language of Black Country men and women, I cannot allow that they are as miserable as one might fancy, and I am certain that they are not so bad as strangers would think. I have known men and women in those depths of society, more true and honest than the majority of their superiors; and it may be prejudice, but had I to choose between living with purse-proud, stuck-up tradespeople or with labouring men, perhaps I should prefer the latter.

Years ago, when a little child, I lived in a small village in Staffordshire, on the borders of Warwickshire, Worcestershire and Shropshire: a poor old man lived near whom I knew most intimately until his death, ten years ago. He was one of the most perfect gentlemen whom, in the course of a varied and busy life, it has ever been my privilege to know, and in many respects he was a second Isaac Ashworth. Archdeacon Hone knew the old shoemaker well, and had done so for forty years; he only needed to call that saintly peasant to mind to justify his indignant defence of his humbler neighbours. As I write, he seems to stand before me with his clear, rosy complexion, genial, sunny smile, contented, happy voice, and winning grace and courtesy of manner. His delight to see me was always unaffected and touching, and after I left the neighbourhood I felt that I had a friend there whom neither time nor distance would ever estrange. Once, after a long absence, I made my way to the little village in which I had lived for eight years, and as I approached his cottage door saw the old man looking out in the twilight. As soon as he caught a glimpse of me his face lighted up with an emotion which became too great for words, and quite choked his utterance. And not long before his death, when I wished him farewell for the last time, his tenderness and love were shown in his wonted touching and refined manner, but with greater solemnity. He had never wandered ten miles from his home, though he lived to be nearly ninety; he had never mixed with the great world; never even been a gentleman's servant, perhaps he would not have been a gainer morally had he been; simply a working man, not earning at his best more than fifteen shilling a week, often less. And yet he was shrewd and clear-headed, a kindly observer of human nature, gentle, upright and pure, one of Nature's gentlemen, on whom the Light of God had descended, and who, in his simple fashion, reflected the Christian graces. Born a churchman, he remained one to his life's end; and, hardly competent to judge of conflicting creeds and to weigh abstruse doctrines, went to the ancient parish church regularly, content to do his duty by all men. Often have I seen him there getting good and doing good to others and feeling that he was in his right place. Poverty came at last, as it generally does to his class, and he had to get parish relief, but he neither repined nor felt degraded; he was thankful for the mercies he had enjoyed, and ten thousand times happier than many a proud noble and self indulgent plutocrat, and when the Great Day comes that good old man will not lose his reward. How different would his life have been had not his guiding star been pure and undefiled religion, and had his faith in the wise purposes of God been rudely shaken.

I also knew in the same village another man, a hammer-maker, recently dead—tall and handsome—a splendid workman, incomparably a more gifted man naturally than many of my old Oxford friends. He was an artist, and had all an artist's pride in his work. Nothing was too hard for him; he moulded iron and steel with the same graceful facility as the master smiths of the Middle Age. He never rose to distinction, indeed he did not wish to rise, but in the little workshop of the factory, where he passed thirty years or more, and of which he was the model workman, he solved many a problem, and accomplished many a difficult task. He was not an abstainer, indeed he rather despised those who needed the protection of the pledge, but no public house ever took his large and well-earned wages; no coarse language ever fell from his lips; no degrading amusements had any attractions for him. He died rather suddenly in the prime of life, at any rate before reaching fifty, and his whole week day life, for over thirty years, was passed between the workshop and his garden; going straight from the forge to the latter and back again. His Saturday afternoons and his rare holidays were spent in his garden, and there he brought the same devotion, the same artist's fancy, the same orginality as to

what was more properly his life work. His were always the finest and earliest potatoes, the most splendid beans, the largest and sweetest peas, the best flowers, and the biggest gooseberries, strawberries and currants. A many-sided man; keen, shrewd, just and upright; continuous work was his delight, and his splendid frame enabled him to rise early and late to take rest, though perhaps he wore himself out prematurely. I cannot see how these two men could have been happier—would that more imitated their simple virtues.

Thus do I perceive that accounts, true to the very letter, of the condition and surroundings of great classes may convey false impressions to strangers. It is necessary to place one's self in imagination in the midst of the class described, and to feel like its members. Macaulay's brilliant pictures of the present century may be literally true, and so, in a different sense, may be Froude's and Hallam's description of the past, so may Kingsley's of the Devon men of three hundred years ago. Dress and externals do not constitute what is best and noblest in man. Everything must be taken into account—manners, pursuits, opportunities, feelings, aspirations, and surroundings; then only dare we assert that the sum of human happiness is getting greater or less. Generally speaking, those who know most and have seen most are happiest and wisest; but there are many exceptions. Knowledge is power, but power sometimes means distress of mind. Was not the knowledge of good and evil purchased by expulsion from the Garden of Eden?

As bearing on the present condition of English society, with its intense selfishness, fierce competition, unconcealed struggles, and rapid increase of wealth and population, the following extract from John Stuart Mill's "Political Economy" is of great interest. No thinker and politician was more free from blind veneration for the past, and unreasoning admiration of the present, and so he was better able than most men to estimate how vast might be the interval separating the activity and distractions of modern life from the calm repose of a prosperous and happy tone of society. "I cannot regard," he says, "the stationary state of capital and wealth with the unaffected aversion so generally manifested towards it by political economists of the old school. I am inclined to believe that it would be, on the whole, a very considerable improvement on our present condition. I confess I am not charmed with the ideal of life held out by those who think that the normal state of human beings is that of struggling to get on; that the trampling, crushing, elbowing, and treading on each others heels, which form the existing type of social life, are the most desirable lot of human kind, or anything but the disagreeable symptoms of one of the phases of industrial progress. The northern and middle states of America are a specimen of this stage of civilization in very favourable circumstances, having, apparently, got rid of all social injustices and inequalities that affect persons of Caucasian race and of the male sex, while the proportion of population to capital and land is such as to ensure abundance to every able-bodied member of the community who does not forfeit it by misconduct. They have the six points of Chartism, and they have no poverty; and all these advantages do for them is that the life of the whole of one sex is devoted to dollar-hunting, and of the other to breeding dollar hunters. This is not a kind of social perfection which philanthropists to come will feel any very eager desire to assist in realizing. It is only in the backward countries of the world that increased production is still an important object; in those most advanced, what is economically needed is a better distribution, of which an indispensable means is a stricter restraint on population. Levelling institutions, either of a just or of an unjust kind, cannot alone accomplish it; they may lower the heights of society, but they cannot raise the depths. There is room in the world no doubt, and even in old countries, for an immense increase in population, supposing the arts of life to go on improving, and capital to increase. But, although it may be innocuous, I confess I see very little reason for desiring it. The density of population necessary to enable mankind to obtain in the greatest degree all the advantages both of co-operation and of social intercourse has, in all the more populous countries, been attained. A population may be too crowded, though all be amply supplied with food and raiment. It is not good for a man to be kept perforce at all times in the presence of his species. A world from which solitude is extirpated is a very poor ideal. Solitude, in the sense of being often alone, is essential to any depth of meditation or of character; and solitude in the presence of natural beauty and grandeur is the cradle of thoughts and aspirations which are not only good for the individual, but which society could ill do without. Nor is there much satisfaction in contemplating the world with nothing left to the spontaneous activity of nature; with every rood of land brought into cultivation which is capable of growing food for human beings; every flowery waste or natural pasture ploughed up; all quadrupeds or birds, which are not domesticated for man's use, exterminated as rivals for food; every hedgerow or superfluous tree rooted out, and scarcely a place left where a wild shrub or flower could grow without being eradicated as a weed in the name of improved agriculture. If the earth must lose that great portion of its pleasantness which it owes to things that the unlimited increase of wealth and population would extirpate from it, for the mere purpose of enabling it to support a larger, but not a better or a happier population, I sincerely hope, for the sake of posterity, that they will be content to be stationary long before necessity compels them to it."

Whatever might once have been the case, how much is now done for working men—excellent popular free lectures everywhere, institutes, museums, fêtes, concerts, parks, excursions, cheap newpapers, literature offered at prices so low that if the mechanic will only give up his pipe he can have his daily paper, and if he will do without his beer he could every week buy one of the masterpieces of literature, which would be a joy to him for ever. As for workers among the poor, let the doctors, the sisters, the philanthropists tell. Nor are these generous toilers generally taken from the humbler grades and only hired for money. How many ladies of noble birth have given up all that seems most attractive at the call of duty. How often I have seen, to cite one instance among many, a lady, the daughter of an earl, working tenderly in the children's hospital, in which she has lived for years, cut off from home pleasures and from the congenial society of her own class. Sister Alice Mary gently and sweetly obeys her self-appointed mission. She takes the fretful little sufferers to her lap, and soothes them for hours at a time, shedding around the blessed sunlight of her love and self-sacrifice, and adorning the doctrine of her Saviour by the practical fruit of her own spotless and unselfish life: earthly rank is laid aside, and as a modestly-habited sister she, like hundreds of others, lives out her days, happy in the consciousness

that she is discharging her lofty mission. Can we despair of our countrymen while such strenuous efforts for their good are being made? Can we brand the age altogether as selfish and dead to duty?

Progress in the arts and sciences is imperative, and will go on. We may be sure of that. It may be indubitable that those reforms from which so much has been expected have often, when carried into practice, left things as miserable as ever. In spite of disappointment and failure man must advance. An evil pointed out must be resolutely attacked; social disabilities must be swept away, and the most complete equality, compatible with the continuance of society on a sound basis, must be the order of the day. As in science the goal of the discoverer to-day is his starting-point to-morrow, so the evils which the social reformer finds he must toil to remove, though admitting that human nature is incapable of absolute perfection. Every time we are told of evils that weigh down great classes the hour of inaction is past, the moment of activity come. I know not whether man's greatest happiness may not be intended by the beneficent Father of all to consist in trying to improve the condition of his less-favoured fellows; and if my surmise is well grounded, what signifies it that, as an able living writer has despondingly said, many of those schemes from which he and others expected so much, such as the Reform Bills of 1832 and 1868, have accomplished little for the regeneration and elevation of the working classes. The striving to do good must bring happiness, and in the path of duty true joy is always found. What social reformers and philanthropists have from time to time said of the horrors amidst which many of the working classes exist must compel us to put forth redoubled efforts, and force us, for example, to remove fever nests and filthy hovels, although their miserable inhabitants are not conscious of their degradation. We have a sacred trust, and we dare not shrink from it. As soon as we know how, we are bound to check preventible disease, and to make it possible for men to live out their days in health and plenty, though possibly the sum of human happiness and contentment may seem to be little increased thereby. It is our duty to inculcate the highest tone of honour, and the purest form of religion, and the All Wise will not exonerate us if we fail in doing all we can.

The aggregation of myriads in great cities, the squalor of their homes, the hopelessness of their surroundings, the misery of never seeing the health-giving country in its glorious solitudes, these are evils we are called upon to remedy as much as circumstances will admit. But the social reformer alone can do little. He must labour in conjunction with the minister of the Gospel, the instructor of the young, the political economist, and the sanitary reformer. The Act of Parliament making education compulsory must be supplemented by the teachings of those whose glorious privilege it is to remind the world that after this life comes another, of which the present is only a part. The Bill giving town councils power to remove squalid courts and filthy alleys must be assisted in its operation by wise guides telling the poor how to keep new and better houses comfortable and pure. The warnings of medical officers of health must be received by men who can understand and appreciate what is being attempted on their behalf. It is a narrow view of the social problems of our age to suppose that a few great reforms will make the masses and the dominant classes happy and prosperous. The great reforms of the past have not been sufficient, and those of the present and the future will be disappointing, unless by their continued action on the understandings and hearts of all they raise the nation, and give all, from the lowest to the highest, loftier conceptions of life, higher aims, and greater peace of mind. Let us not fancy that public health acts, or education bills, or coöperation, or permissive bills, or any other scheme alone or altogether, will suffice. The problems of life are terribly difficult, and for their elucidation ripe knowledge and immense labour are needed. There is something inexpressibly solemn and affecting in the death scene of that stern though grand Calvinist—Mr. Leyburn—as described by Mrs. Humphry Ward. "Catherine," exclaimed the dying clergyman, "life is harder, the narrow way narrower than ever. I die," and memory caught still the piteous, long-drawn breath by which the voice was broken, "in much, much perplexity about many things. You have a clear mind, an iron will. Strengthen the others. Bring them safe to the day of account." "Yes," she answered, "father, with God's help, oh! with God's help." Again, continues Mrs. Humphry Ward in the same remarkable, though unsatisfactory and to many most painful work, "The Ritualist may glory in the discomfiture of an Erastian bishop; what Christian dare parade ten years of love to God and man," but may I not add, who but the Christian would devote himself to the ungrudging service of mankind in the Master's spirit?

If I read aright the utterances of profound thinkers, I believe that, with few exceptions, they, in the main, endorse the view I have in this and in many other articles taken, and I find that many distinguished friends of mine repeat in their private letters what in public they often state—that the very abundance of the labours of the past has bequeathed to us a still larger debt to discharge. We are the heirs of the knowledge of the past, and we know better than our predecessors the magnitude of the task before us; with more to do there is a still more urgent call to lose no time in beginning the work—its completion our descendants must take in hand and try to accomplish. No, the improvement of the moral and social condition of our countrymen is not easy: it requires the coöperation of philanthropists and reformers, and among them the leaders of sanitary science occupy a leading position; it demands the unselfish, loving, ungrudging coöperation of an enlightened clergy, emancipated from the detestable, worn-out rags of prejudice and narrowness. The field is vast enough to enlist all the workers, and to fill all the best thoughts of the age; but one class cannot do without another, and unless all pull together, the unaided exertions of one body of reformers will accomplish little. Infidelity is growing; population is increasing by leaps and bounds, and the disintegration of classes, especially in towns, is going on apace. Never was there more to do; never was it better known how to work; and, alas! that I should have to say it, perhaps never were unchristian class distinctions pushed to more unjustifiable extremes; and never were religious conflicts more formidable obstacles. S. U. M.

URN-BURIAL.

By W. Armstrong Willis, Monmouth.

A large literature, ancient and modern, exists on the subject of urn-burial; the older writers discoursed learnedly on it, and used it as a peg on which to hang evidences of their recondite learning, illustrated by apt quotations from obscure authors. With the moderns,

under the aspect of cremation, it has been treated with all the lights that science and sanitation can throw on it. To a civilised community, dealing with its dead is of the first importance; that illustrious scientific men amongst us are dissatisfied with existing methods is familiar to most, and proves the matter worthy of thoughtful interest. It must be agreed that on no other subject have such masses of painful and revolting information been so freely given to the world, as in the many newspaper controversies on the question of burial which have occurred in the last few years. These open discussions in a measure did good; popular favour has been turned against the abominations of brick graves and leaden coffins, and much of the unmeaning mummery of the undertaker can now be dispensed with by more tasteful minds, without unduly scandalising the conventionalities. The subject of burial quite recently appears before us again in the Returns, issued by the Government, having reference to interments in London cemeteries, published in answer to a request of the Burial Reform Association, a society which advocates what is called "earth to earth" burial. These returns show a great over-crowding of the dead in the midst of a large living population. In the Brompton cemetery, with an ever-growing population around it, in an area of less than twenty-nine acres, have been buried since June 18th, 1840, 155,064 bodies; in the Tower Hamlets cemetery, in an area of about seventeen acres, have been buried since 1841, 247,000. The common interment system, called in Scotland pit-burial, in which a very considerable number are buried in the same grave or trench, is observed in every London cemetery, and notably in the Brompton one, where 100,000 are buried on this system. The total number buried in the suburbs of London during the last half century, for the most part in durable coffins in unsuitable graves, is considerably upwards of a million and a quarter. The annual death-register of Great Britain is close on 700,000; allowing ten years for the complete resolution of the body, under present conditions of burial, gives nearly seven millions of dead bodies in various stages of decomposition, emitting noxious exhalations to the atmosphere, and contaminating the subterranean water-reservoirs. Figures are often uninteresting, but these statistics of our own "Nations of the Dead" speak for themselves; their bare numbering strengthens the position of the cremationist as one thinks of this great multitude, larger than any fabled army of ancient history, festering under a few feet, more or less, of earth. Probably the population of Great Britain will never be as dense as that of districts in China, a country which well exemplifies the serious disadvantages of long-continued earth-burial. In Mr. W. Robinson's recent book, "Cremation and Urn-burial," a forcible and practical work, abounding at the same time in varied and curious information (of which the writer of this article has freely availed himself), there is to be found a long account of burial in the Celestial Empire. In the country, near Shanghai, the land is one vast grave-yard. Everywhere, almost in every field, are graves in mounds of earth, or coffins standing exposed on four legs. These coffins remain for some time exposed, and are afterwards buried or set on the ground, and a large mound piled over them from two feet to five feet high, and seven feet through. All round the walls of Ichang is this graveyard, notwithstanding that the land is agriculturally valuable and there is a dense population. There are always dozens of dogs in these cemeteries, and they may be seen devouring the recently buried bodies—a horrible sight, but familiar to travellers in various parts of China. Outside the town of Chin-Kiang, on the river Yangtse, are low hills of considerable extent, covered with the graves of men who fell in the Taiping Rebellion; each is marked by a little mound of earth, covered with rough grass, no cultivation whatever being attempted. The graves of the Mandarins or high officials take up more space. Near Nangkin are the Ming tombs, where monster stone figures are set up on each side of the road leading to them; smaller effigies of men, horses, lions, and elephants, guard the approaches to the tombs of old rulers and warriors; by these an enormous extent of valuable land is kept out of cultivation and becomes the home of pheasants and hog-deer. Such graveyards help to make China the sad, unpleasant country it is; the insufficient modes of burial render great tracts of land unavailable for ornamental or useful purposes, and offer a variety of disgusting sights to the living. It is a relief to turn from China to Japan; here the dead are burned, and the land saved for the pleasure and profit of the living, and the small cemeteries are beautiful. A charming spot is generally chosen; sometimes in a lovely valley, shaded by enormous pines, or sometimes little lawns or ledges on the hillsides. Each family using the cemetery has a small plot of ground, in which the ashes are buried. There is, of course, a great saving of land compared with the Chinese, or even with our own method. Over the buried ashes is a stone, often beautifully cut, containing the name of the family or individual, while vases for flowers and lamps are to be seen near the graves in these beautiful cemeteries. The evergreen bushes planted in these spots are the ilicium religiosum, the tea-shrub, camellias and euryia japonica; specimens of the maidenhair tree or ghinko (Salisburia) may be also seen, with noble umbrella pines and other rare trees. Such are the surroundings which the most æsthetically-minded people of the world choose and artistically dispose around the ashes of their dead. We may well ponder if in this matter Europeans might not with advantage imitate the practice of the tasteful and simple Japanese. It is doubtful if anything can be more distressing than the dreary stone-yard which does duty as an average English cemetery. Monuments of unmeaning design, weighty iron railings enclosing patches of white marble pebbles (crushed to resemble lumps of sugar), tributes of wreaths of painted tin flowers, and other abominations, make it the dreariest place imaginable. On the Continent, where we fondly believe there is more recognition of the craving for the beautiful, things are still worse. Père la Chase can show nothing better than acres of mean memorial stones and chapels, the whole plentifully strewn with wreaths of blackened, decaying "immortelles." The treatment, in Parisian cemeteries, of the portion reserved for those who have not obtained a concession in perpetuity for their dead, is extremely painful. After a certain number of years the ground is cleared out, dug up, and used again. The wooden crosses, little head-stones, and countless ornaments are carted away or thrown together in great heaps; the crosses and consumable parts being generally sent to the hospitals as fuel. The headstones from such a clearance (when not claimed) go to make the drainage of a road, or are used for some similar purpose. In England, also, this destruction is not unknown, mural monuments inside ecclesiastical buildings often faring as badly as memorial head-stones in the churchyard. As every clergyman is, *ex-officio*, possessed of taste and competent to direct and set on foot that strange process now known as a "restora-

tion," it follows that his cultured eye dislikes the mixed styles of the Tudor, Jacobean, and Georgian monuments in his chancel; they are to him barbarous relics, and as such to be hustled away to the belfry and other obscure places, and the church left in the grim bareness of its newly-scraped, blank walls. Some people are so constituted as to regret deeply this destruction of the memorials of the dead, and the moving of their remains from the original position in which they were first laid. It is curious that an age which glories in its utilitarianism has not been more ready to adopt urn-burial; to the practically minded it cumbers the ground less, and has sanitary and economic advantages, while the more sentimental could rejoice in the perpetuation of the memories of their friends in beautiful and lasting receptacles for their ashes. The practice of cremation would, for the survivors, rob death of some of its ghastliest terrors, and they are, in these matters, to be chiefly considered. An old divine beautifully says of the dead, "To them it is all one, whether they be carried forth upon a chariot or a wooden bier, whether they rot in the air or in the earth, whether they be devoured by fishes or by worms, by birds or by sepulchral dogs, by water or by fire, or by delay. . . . There is nothing in this but opinion and the decency of fame to be observed."

By the adoption of urn-burial, all that concerns the artistic side of the cemetery would be changed. One of the larger burial grounds, now closed, perforce, in a time less than an ordinary life, would suffice for the burial of many ages, under the altered conditions. The present tendency to neglect and desecration would be counteracted by the fact that each living generation would be as much interested in the care and keeping of the cemetery as those that had gone before. This gives at once what is an absolute necessity from the artistic and sentimental point of view—absolute permanency for the resting-place of the dead. That charming author, Dr. Oliver Wendell Holmes, was moved to indignation by the removing and alteration of monuments in America, and wrote as follows: "The most accursed act of vandalism ever committed within my knowledge was the uprooting of the ancient grave-stones in three at least of our burial-grounds, and one at least just outside the City, and planting them in rows to suit the taste for symmetry of the perpetrators. The stones have been shuffled about like chessmen, and nothing short of the Day of Judgment will tell whose dust lies beneath any of those records, meant by affection to mark one small spot as sacred to some cherished memory. Shame! Shame! Shame! that is all I can say. It was on public thoroughfares, under the eye of authority, that this infamy was enacted. I should like to see the gravestones which have been removed or disturbed, and the ground levelled, leaving the flat tombstones. Epitaphs were never famous for truth, but the old reproach of 'Here lies' never had such a wholesale illustration as in these outraged burial-places, where the stone does lie above, and the bones do not lie beneath." This passage, so fiery for the most genial of writers, might be carefully studied by the philanthropists who enjoy turning London churchyards into playgrounds. If permanency were obtained, the knowledge that our cemeteries would be sacred for all time and jealously guarded, would influence those who would find in them a new field of art-work. The great revival of taste has caused the most careful attention to be bestowed upon the designs of the merest trifling details of our houses and life; this would be extended to the urns and rest-gardens of our dead. The gruesome meretriciousness and temporary handsomeness of the varnished wooden coffin, and its plated fittings, are not pleasing objects for the eye to dwell on; smothered with flowers it is just passable in its ugliness. But who can walk through any museum or collection without being struck with the beauty of the ancient urns? Without mentioning in detail the noble urns of the Vatican and Borbonico Museums, there are lovely specimens in our British Museum, of all shapes, simple and intricate, plain and decorated, of marble and porphyry, of terra-cotta and of glass. It was a Grecian urn which inspired Keates with the well-known poem, opening, "A thing of beauty is a joy for ever." The urn of the pauper might be as perfect in its curves and proportions as that of the greatest prince, although in material and decorations they should differ. In building tombs and columbaria for the reception of urns, the wealthy patrons of art could encourage the creation of magnificent edifices. For people of purer and simpler taste, a plain tomb placed among groups of rarest trees, forming a delicious feature in the landscape of the country, the park, or the garden, might make the home of the ashes of the pioneer in far-off lands, or of the soldier who had fallen in the Tropics, which could be brought back without painful effort to rest among their kindred. Such places would be a fitting resort for the living, for meditation, aspiration, and prayer. One such spot in the midst of a busy town would form the text of a continuous sermon, such as no city grave-yard can preach. In our wealthy communities all that is noble in sculpture, painting, and mosaic would come naturally to the ornament of such buildings; cloisters might be used, and portions of our cathedrals and churches adapted for the reception of urns. Around the new buildings, if possible, there should be lawns and groves, and the best loved and most illustrious should be commemorated in groups or single specimens of fine trees. Nothing trifling, nothing frivolous, or incongruous, should be admitted, and these places would be not only resting places for the dead, but would grant a measure of peace to the living. Never again would the prying antiquary or fanatic revolutionist be able to desecrate the actual bodies of the dead.

There exists rather a rare *brochure* detailing the violation of the royal sepulchres at Saint Denis, during the French Revolution of 1793. The body-snatchers set to work in the October of that year, and their labours occupied the whole month. The first corpse found was that of the once loved Henri IV. (Henri de Navarre). As a king who had been popular with his humbler subjects, his corpse was specially well-treated by the crowd, who propped him up in his shroud against a wall. One of the Republican Guards cut off the king's grey up-turned moustache, and placed it on his own lip; another removed the beard, to keep or sell as a relic. Having paid these marks of attention, the body was thrown into a huge pit, filled with quicklime, into which successively his ancestors and descendants followed him. Next day the corpse of Henri IV.'s wife, Marie de Medicis, and that of his grandson, Louis XIV. were added to his. The body of the "Sun King" (as Louis XIV.'s courtiers loved to call him) was "black as ink." What a contrast must this poor blackened old skull have been, to the majestic periwigged head which still looks down patronizingly from the canvases of Le Brun and Rigaud in the French palaces. So this noisome work went on methodically, till all the Bourbons had been disentombed; then the lines of Valois and Capet came in turn, until the almost legendary remains of Dagobert

appeared. A pause was made before opening the coffin nearest the door of the royal vault, which contained, according to custom, the king who had died last. Louis XV., "*le bien aimé*," had perished of a most terrible disease, and it was rumoured that the undertaker who tumbled him into his coffin had perished by contagion. It was only therefore on the edge of the pit that the revolutionists removed the body from its coffin and hastily rolled it in, but even with the precaution of discharging guns and burning powder, the air was horribly tainted, even to a distance. The whole story is sickening in its monotony, which is only relieved by the details of the more or less advanced states of decomposition of the poor royal remains. From this one learns that the horrors of decay last after two or three centuries of burial, and a body thus coffined being removed "a black fluid, emitting a noxious smell," will run from our last home, as was the case at Saint Denis at this ghastly unburying of great people in 1793. It is needless to quote accounts of the disinterments of the Cromwellian regicides for political purposes, or of the opening of the coffin of Charles I., at which George IV. assisted. Cremation would have rendered such scenes impossible, and left a pleasing blank in the darker pages of history. No better conclusion to an article on this subject can be found than a quotation from that quaint treatise on "Hydriotaphia, or Urn-burial," by the learned writer and physician Sir Thomas Browne. It may be incidentally remarked how well his words apply to that strange burning of the body of the poet Shelley, at Spezzia, by his friend Trelawney. The great writer in his concluding passages on Urn-Burial, says: "Life is a pure Flame, and we live by an invisible Sun within us. A small Fire sufficeth for life, great Flames seemed too little after death, while men vainly affected precious Pyres, and to burn like Sardanapalus. But the Wisdom of Funeral Laws found the folly of prodigal Blazes, and reduced undoing Fires unto the rule of sober obsequies, wherein few could be so mean as not to provide Wood, Pitch, a Mourner, and an Urn."

OXFORD: ITS COLLEGES AND HALLS.

By Alfred J. H. Crespi, of Wimborne.

The recent revival of the Oxford School of Physic and the increasing attention paid in that University to natural science are sure to lead to a considerable influx of undergraduates intending to join the medical profession, and no better training for a young man of means, and wishing to confine himself to good class large town practice, could be conceived. Whether, however, five or six years at Oriel, Christ Church, Merton or Balliol is the best preparation for a club doctor, is a totally different matter. The rich are few, the poor many, and most medical practitioners must look for a scanty living from patients, who think in pence rather than in shillings; and unless I am greatly mistaken, I believe that some members of the medical profession could be pointed out who have lost more than they have gained by a University course, and have had reason to regret that their heads were then filled with notions that did not accord with their surroundings in after life.

It is difficult for anyone, not a member of one of our two ancient Universities, to understand the friendship and brotherhood commonly subsisting among Oxford men. Wherever the various chances of life may lead the Oxonian, and whatever the scenes that may surround him, he looks back with an affection and veneration incomprehensible to others, to the time-honoured colleges and halls in which he passed several happy years. Nothing precisely similar obtains in the learned professions at large. The medical student rarely looks back to his hospital with more than passing interest, and does not always even care to revisit it; the barrister and the dissenting minister do not feel their hearts stir within them as they recall the scenes of their early professional studies; and army officers are, perhaps, the only large professional class which proudly remembers its early associations; they never forget their old companions in arms—never tire of talking about their old regiment, just because a regimental mess has much in common with life in hall.

The Oxonian always clings to his dearly-loved college. Again and again, when opportunity permits, he retraces his steps to the familiar quadrangle, and lives again for a few moments in the far-off time when he was an undergraduate. The hold Oxford has on the minds of its alumni is extraordinary, and is one of its most precious fruits. It is the best result of the inimitable system of education which makes of the members of the respective societies one great family, with interests in common, and which regards the prosperity of one of its members as the glory of all.

Sir George Trevelyan in the following passage has given Lord Macaulay's views on the matter: "He keenly appreciated a society which cherishes all that is genuine, and is only too outspoken in its abhorrence of pretension and display: a society in which a man lives with those whom he likes, and with those only; choosing his comrades for their own sake, and so indifferent to the external distinctions of wealth and position, that no one who has entered fully into the spirit of college life can ever unlearn its priceless lesson of manliness and simplicity. Of all his places of sojourn during his joyous and shining pilgrimage through the world, Trinity, and Trinity alone, had any share with his home in Macaulay's affection and loyalty. To the last he regarded it as an ancient Greek or a mediæval Italian felt towards his native city. As long as he had place and standing there, he never left it willingly, or returned to it without delight. The only step in his course, about the wisdom of which he sometimes expressed misgiving, was his preference of a London to a Cambridge life. The only dignity that in his later days he was known to covet was an honorary fellowship, which would have allowed him again to look through his window upon the college grass-plots, and to sleep within sound of the splashing of the fountain; again to breakfast on commons, and dine beneath the portraits of Newton and Bacon on the daïs of the hall; again to ramble by moonlight round Neville's cloister."

In my case my heart clings to Oxford. I recall with undiminished pleasure the courtesy and refinement of its more polished members. I still seem to listen to the graceful and stately eloquence of its profound and eminent preachers. I look back to its delightful life, unique in its character. Wherever I wend my steps, the hallowing and chastening influence exercised by some residence within its venerable walls, and in the atmosphere of its noble halls and colleges, remains fresh and imparts an interest and dignity to life, when anxiety and disappointment, and the duties of a profession for which I have no aptitude, and small liking, might press heavily on me.

The University of Oxford is an institution of extraordinary antiquity. Tradition ventures to claim for King Alfred in 871, the proud honour of laying the foundation

of that glorious and incomparable system of education of which Englishmen are so proud. Without going back to the great West Saxon King, traces can be discerned of educational institutions existing at Oxford many centuries ago. There is reason to believe that, for eight hundred years, classical learning has flourished on the banks of the Isis, and as long since as 1249, William of Durham, Archdeacon of that city, and rector of Wearmouth, bequeathed a sum of money to University College. It was not, however, till about 1270 that Walter de Merton, Lord High Chancellor of England and Bishop of Rochester, established the first collegiate institution, in the present acceptation of that peculiarly English term, at Oxford. The college he founded still keeps his name alive. From his day a long succession of colleges has been established. There are now twenty-five public colleges and halls, each forming a complete society, and training large members of the ablest and most promising young men of the nation, who perpetuate the glory, and diffuse the fame, refinement, and influence of Oxford wherever they go.

The colleges have not the power of examining for and granting degrees, which are only conferred by the University; the latter examines candidates through its deputies, who are eminent men impartially and carefully selected from the members of the colleges. The University, in its collective capacity, comprises all the members of the colleges and halls, as well as the unattached students: it regulates and carries on the general training and education of the undergraduates. But every college controls, to some extent, its own affairs, and it watches over the interests and conduct of its members. The University is governed by distinguished men, selected from the great body of graduates, but every society governs itself by its head, fellows, and tutors. Except in Dublin, no system remotely similar exists anywhere out of this country.

The fame of some colleges much surpasses that of others, and although every undergraduate must pass through the portal of the University public examinations before he receives a degree, and even unattached students sometimes take a "first class," one college may, and often does, as the reward of abler management, more distinguished tutors, or more liberal endowments, attract an exceptional number of talented young men, ten times as many as may enter another college in the same street. The prestige of a college tends to increase and perpetuate itself, and when at last the roll of its celebrities includes scores of the most famous names in the country's history, it may consider it no slight honour to admit any but the most promising young men from the public schools. In every branch of science, in every walk of literature and art, in every century, in every Parliament, Oxford names shine prominently. Oxford points with maternal pride to the glorious names of Friar Roger Bacon and Edmund Halley, the astronomers; she claims John Locke, the mental philosopher; Adam Smith, the political economist; Richard Hooker and Joseph Butler, the theologians; John Hampden, the patriot; and Shelley, Southey, and Chaucer, the poets. It was she who trained Sir Matthew Hale, the upright judge; Dr. Thomas Sydenham, the learned physician; and Lord Chancellor Clarendon, the historian. Edward Gibbon, James Anthony Froude, Edward Freeman, Addison, Keble, the Newmans, Samuel Wilberforce, and Reginald Heber, the Arnolds, Sydney Smith, and Thomas de Quincey, all had their minds formed at Oxford. From her halls went forth John Wycliffe, that sturdy and chivalrous champion of untrammelled and enlightened thought. From the same halls have also issued those bigoted upholders of regal tyranny and priestly intolerance and assumption, of whom Cardinal Wolsey and William Laud, Archbishop of Canterbury, are among the most illustrious. Oxford has always been proud of its famous bishops and divines, from the distant days of Cardinal Morton and the more recent times of Bishop Prideaux, to the present generation, when she points to Dr. Newman, Dean Stanley, Bishops Wilberforce and Temple, and Archbishops Whateley and Tait. Oxford is also proud of its accomplished statesmen, and claims, among the leading men of the day, Mr. Gladstone, Lord Sherbrooke, Lord Coleridge, Lord Salisbury, and Lord Selborne. High in authority among the bishops, deans, ministers of state, judges, and writers, of whom England is proud, are so many Oxford names that one is half forced to the conclusion that there is some mysterious connexion between English University life and subsequent fame. It is significant that the majority of Englishmen of preëminent ability and influence have belonged to Oxford or Cambridge. It is quite an exception to find writers and public men ranking so high among the notabilities of the age as John Stuart Mill, Dr. Carpenter, Charles Dickens, Joseph Chamberlain, and John Bright, who have not studied at one or the other.

A singular instance of the injustice of accusing Oxford of producing nothing but illiberal priests is that, although the great heads of the Ritualist party, Drs. Newman, Manning and Pusey, and John Keble, were trained at Oxford, the heads of the Broad Church, Frederick Denison Maurice, Thomas Arnold, Dr. Whateley and Benjamin Jowett, were also graduates of this university, though the first was educated at Cambridge.

The city is not less striking than its life, and one of Macaulay's letters to his sister Hannah gives a lively sketch of it. He says "I came through Oxford. It was as beautiful a day as the second day of our visit, and the High-street was in all its glory. But it made me quite sad to find myself there without you and Margaret. All my old Oxford associations are gone. Oxford, instead of being as it used to be, the magnificent old city of the nineteenth century—still preserving its antique character among the improvements of modern times, and exhibiting in the midst of upstart Birminghams and Manchesters the same aspect which it wore when Charles held his court at Christ Church and Rupert led his cavalry over Magdalene Bridge—is now to me only the place where I was so happy with my little sisters. But I was restored to mirth, and even to indecorous mirth, by what happened after we had left the fine old place behind us. There was a young fellow of about five-and-twenty, moustachioed and smartly dressed, in the coach with me. He was not absolutely uneducated; for he was reading a novel, "The Hungarian Brothers," the whole way. We rode as I told you through the High-street. The coach stopped to dine; and this youth stopped half an hour in the midst of that city of palaces. He looked about him with his mouth open, as he re-entered the coach, and all the while that we were driving away past the Radcliffe Library, the Great Court of All Souls, Exeter, Lincoln, Trinity, Balliol, and St. John's. When we were about a mile on the road he spoke the first words that I had heard him utter. 'That was a pretty town enough. Pray, sir, what is it called?' I could not answer him for laughing, but he seemed quite unconscious of his own absurdity."

As we approach Oxford by the Iffley-road, and cross the splendid bridge which spans the Cherwell, we enter a new

world, unlike all other phases of English life. On the right stands in solitary grandeur the lofty pile of Magdalen, with its majestic clock tower, magnificent chapel, splendidly decorated cloisters, and exquisite gardens. If we turn into the cloisters we are in the midst of mediæval England. How wonderfully beautiful is every object! how stately and imposing the ranges of colossal buildings and sombre rooms! As we pass through the cloisters, and reach the beautiful avenue of trees known as Addison's-walk, fancy takes us back long centuries in our history. All else in England is changed, or is fast changing. But in this busy, restless, nineteenth century, Magdalen College survives in its ancient loveliness, a relic of the earlier part of the Middle Age. It is elsewhere usually difficult to realise that our feet are actually resting upon the very soil once trodden by the great men of old. Here, as we slowly pass under the glorious network of trees, we *know* that Joseph Addison, and before him, John Hampden, delighted to wander and think. In the gardens and cloisters of Magdalen everything is tranquil and peaceful; the cares and anxieties of a trying professional career are forgotten, and one can calmly think for a brief season, oblivious of the noise, turmoil, and competition of daily life. If evening be approaching, we can come out of the gardens and walk through the cloisters to the noble chapel, and there listen to the solemn notes of the organ and the sweet voices of the singing men, blending harmoniously in the evensong, which for so many years has daily ascended to heaven from its sacred walls. Can anyone be surprised at the soothing influence which the quiet of Oxford exercises?

Reluctantly we leave Magdalen and its beautiful surroundings, and coming again into the High-street, walk in the direction of Carfax Church. Everything impresses us by its antiquity. In a few minutes we pass on the right the imposing pile of Queen's; and on the left, at the same moment, we see, towering into the sky, the majestic and sombre buildings of University, the oldest of the existing societies. In another minute we have on the right the graceful pinnacles and fair fabric of All Souls'; then, on the same side, there faces us in all its architectural splendour, the immense church and tapering spire of St. Mary the Virgin, better known as the "University Church." Its pulpit, for many generations, has, Sunday after Sunday, in term time, been filled by the foremost thinkers of their day. It is here that, in term, are preached the University sermons. To this church the members of the colleges flock in hundreds whenever some great preacher or distinguished leader of intellectual freedom fills the pulpit. To this ancient church come in stately procession the heads of houses, the doctors, proctors, masters, and professors. On every occasion of importance the faces of not a few great scholars are seen within its walls. St. Mary's is worthy of its proud position. For beauty and stateliness it would be difficult to find its equal. In size it is scarcely inferior to cathedrals of the second order, and closely resembles them. Among other objects of interest she points to her beautiful steeple, rising from the intersection of the transepts with the nave and choir to the height of several hundred feet. Reluctantly leaving St. Mary's, we turn in the direction of Broad-street. What a sight meets the eye! We are in a large square, lined on every side with some of the finest buildings in the land. Behind us is the University Church; to the right extend the long ranges of All Souls', and the quadrangle of Hertford College; on the left is the King's Hall and College of Brasenose; in the centre stands the vast dome of the Radcliffe Library, containing tens of thousands of precious volumes; along the far side, and directly in front, are arranged the enormous piles of buildings known all the world over as the Bodleian, that wonderful collection of hundreds of thousands of ancient and priceless works. We pass through the square and ascend the massive staircase of the Bodleian, and along its broad passages. It is difficult to believe that all the books in the world are not disposed on the shelves which meet the eye, look where we will. For acres the walls are covered with tomes and paintings. Half-bewildered, we retrace our steps, and issue into the open air. But the wonders of Oxford are very far from exhausted. Within a few yards of the Bodleian, indeed, in the same building, is the Divinity School, remarkable for its richly-decorated ceiling and air of grandeur, and memorable as the place where the Parliament of England used to meet. Near at hand is the Sheldonian Theatre, one of the finest halls in the land. In it the principal meetings of the University are held, and the annual commemoration is celebrated. Close, too, is the Ashmolean Museum, with its many curiosities. There we see King Henry the Eighth's chair and the famous sword sent him by the Pope. There, too, with deeper pleasure and more unalloyed interest, our eyes rest on the venerable and beautiful Alfred Jewel, a small gold ornament, which tradition permits us to believe belonged to that great monarch.

Leaving the museum, we continue in the direction of the park. On our right we pass another sombre college—Wadham; further on, on the same side, extends that stupendous modern pile—the Natural History Museum: within its walls the scientific instruction afforded by the University is given. In such a structure, so light, airy, and well arranged, arduous study almost becomes a pleasure. The scientific professors are a numerous and distinguished body, worthy of the renown of Oxford.

Directly facing the principal entrance of the museum is a fine range of new buildings, standing out clearly and sharply in the sunlight, to which extensive recent additions have been made; that is Keble, the youngest of all the societies. It was opened in June, 1870, and is intended to keep alive the memory of the Anglican Christianity of the gifted poet whose name it bears.

We return to the Ashmolean; and turning down a street to the left, reach the extensive quadrangles, gardens, and ancient chapel of New College, which might easily engage the attention for hours. Surrounding the gardens is a portion of the old city wall, as perfect as when first erected. To the left are one or two ancient churches, and the little quadrangle of St. Edmund's Hall. Leaving New College, we retrace our steps and go down Broad-street: to the left are the immense piles of Exeter, Lincoln, and Jesus; John Wesley was a fellow of the second: to the right the quadrangles and lovely gardens of Trinity, Balliol and St. John's are picturesquely grouped. In our progress we see the spot where Cranmer, Latimer, and Ridley perished; we also pass the house in which resides that most accomplished and amiable of men, Sir Henry Acland, the Regius Professor of Physic in the University. Leaving these glories behind, we come out into St. Giles's. On every side are imposing buildings and interesting churches; close to the right are the lovely gardens of St. John's among the most beautiful in Oxford; in front the Taylorian rears its huge bulk into the sky; at a greater distance—at the end of Beaumont-street, but not in sight where we

stand—are the gloomy buildings of Worcester, interesting from its extensive gardens and ancient chapel.

Without stopping to examine or to admire, we turn to the left, and in a few minutes, cross High-street, close to Carfax, and, within two hundred yards, approach two more colleges: the smaller, to the right is Pembroke, Samuel Johnson's alma mater: the one to the left, and by far the largest in the city, is Christ Church. We enter the latter, passing under the massive tower, which holds the largest bell in Oxford. We are in an immense quadrangle, with interminable ranges of rooms extending in all directions, and, recalling the many celebrities of this the largest and most splendid of the colleges, we feel that we are treading on holy ground. Many remarkable names are on the college rolls, and indeed, several distinguished men have till recently actually resided within its precincts: two great names immediately occur to the mind—those of Canon Pusey and Canon Liddon, among the most eminent and learned of modern Oxford professors. A little to the left are seen another enormous quadrangle and the splendid college library. On the right, nearly facing us, are the cloisters, and through them we reach the Cathedral. A little farther off, we approach the new ranges of college buildings and the Broad-walk, near which flows that noble and beautiful river, the Isis, as the Thames is called in this part of Oxford. We pass along under the ancient trees, and make our way out near Oriel, the wonderful college which has exercised such subtle and far-reaching influence on English religious thought during the present century. Close at hand is Merton, with its handsome church and long roll of worthies: Close, too, is Corpus Christi, distinguished for the learning rather than the number of its members. Finally, passing along the street in which these colleges stand, we, in a few minutes, re-enter the High-street near Magdalen College, the spot from which we commenced our circuit.

The description I have attempted is far from complete, and is little more than an enumeration of the principal beauties and glories of the colleges, each of which has a long and often chequered history of its own. But I have tried to give my readers some conception of the scale on which Oxford is built, some idea of its principal objects of interest, which may serve to stimulate his curiosity, and tempt him to explore for himself. The search would be fruitful, and would repay the little trouble and expense involved. I love Oxford, and should be delighted to return and spend much of my time within its walls. I always was impressed by its culture and refinement; I am proud of its preachers, thinkers, writers and statesmen; and I am thankful that it fell to my lot to pass a certain portion of my life within its influence.

If Oxford is true to herself, and moves with the times; if she stands up as the fearless champion of freedom of thought, and the leader in matters religious, political, and scientific, her prosperity and influence are assured for centuries. She might again number among her sons many a Wycliffe, many a Hampden, many an Adam Smith, who in religion, politics, and science would be pioneers of progress. If, however, instead of advancing with the times, and tempering with her culture, refinement, and learning the enterprise, research, and democracy of the day, she holds back—still worse, if she tries to check progress and strangle thought—her influence will wane, and her long and glorious career will come to an ignominious end, or she will pass away weighed down with bigotry, and an object of neglect and contempt to the whole thinking world.

THE DOMESTIC WATER FILTER.

By G. F, Cadogan-Masterman, M.D.

Three methods are in common use for the purification of water, and, in the order of their excellence, they are: distillation, ebullition, and filtration.

The first is largely used on shipboard, and in other places where salt or brackish water is alone obtainable; and also, for the ultimate sterilizing of an already fairly pure water, either for scientific purposes, or as a beverage of exceptional purity, such as is sold in New York under the name of "Hygeia Water," and is distilled from that of the Croton aqueduct. The result is a perfectly wholesome drinking water, but "flat" and unpalatable from the absence of air and carbonic acid, and it has been shown that any attempt to remedy this defect by artificial aëration will probably lead to the introduction of the germs it was the special object of the distillers to get rid of; and the water has the singularity—for obvious reasons—of containing more free ammonia than that from which it was derived, which, if its source were not known, might lead an unwary analyst to believe that he was dealing with a specimen dangerously contaminated.

Water which has been subjected to tolerably long boiling is almost equally wholesome, and, if it were previously hard from the presence of bi-carbonate of calcium, would be considerably softened thereby. Any free ammonia would be driven off, and every form of animal and vegetable life be destroyed or rendered inert. But it has, again, the disadvantage of a mawkish taste, which may, however, be covered by using it in the familiar form of toast-and-water, or by the addition of a little syrup of lemon or lime-juice.

The greater part of the water supplied for public use is derived from sources which necessitate filtration on a large scale before delivery, and, as an additional precaution, this is often repeated at home; and it is the domestic water filter I desire to shortly examine and comment upon.

The oldest, and still as far as my observation goes, most generally used, is the familiar stoneware cylinder, of many pretended patents, but one plan: a straining sponge with a sham filter-bed beneath it. A few years since I had the curiosity, and indeed, necessity, to take one from a well-known maker to pieces. On lifting the cover there was seen, about six inches below, a partition with a perforated cup in the centre, filled with a tightly compressed sponge in an advanced stage of decomposition, dark, slimy and evil-smelling. I threw this away, and then, with a narrow chisel and hammer, chipped off the cement and lifted the partition itself. I found beneath, a bed of sand, small pebbles and coarsely broken charcoal, also, some red worms and a gelatinous mass of confervoid and animal matter, which gave off a smell I should be sorry to characterise by too strong a word, and which, after reserving a portion for the microscope, was gladly thrown on the compost heap. Below this was another partition, pierced with fine holes, and then the reservoir for the purified (!) water.

Now it must not be imagined that I found this delectable arrangement abandoned in some dusty shed, or that it was an old one. No, it had been purchased but a year or so before, and had been in constant use up to the day when I disembowelled it, and by a family of scrupulously nice and refined people, who had invoked my aid because they had all been out of health for some time in an indefinite way.

I should add that they were Nephalists, and regarded the filter with most trustful confidence. To avoid distressing them too much I did not tell of all I had found, but advised them in future to use their very excellent well-water exactly as nature supplied it, and with the best results.

I was greatly taken myself with the very neat carbon filters fitted in a glass vase, and for some time one stood on my my dinner waggon for daily use, until some chance reference to the wonderful purifying powers of charcoal, by a visitor at luncheon, led me to explain that in this case it acted simply as a strainer, and I was going to inconsiderately add, as a very perfect one, when a little green discolouration on the inner surface of the receiver caught my eye, and led to the intervention of the microscope, with the discovery—which a little consideration had prepared me for—that, as regarded cell growth, the water above the carbon cylinder was considerably purer than that which had passed through it! and I rather regretted the investment of 7*s.* 6*d.* in an apparatus, which, after two or three vicissitudes, disappeared in the lumber room. From that day I drank water unfiltered and with a normal amount of microbes, and am certainly none the worse for them.

Nearly three years ago I was looking through my monthly bundle of foreign medical papers, and in an Italian journal found a translation from the Russian *Vratch* of an article by Dr. J. Viltchür on this very subject. He had been examining experimentally a number of filters—our old friend the cylinder with the fœtid sponge was passed by with contemptuous disgust—with carbon blocks, silica and carbon, spongy iron, asbestos, and so on; and he found them all more or less imperfect strainers, purely mechanical; when quite new germ traps as well, but after a week's use strainers and germ nurseries—that is, a water containing a known proportion of a given bacillus had that proportion enormously increased by the so-called filter purification. When the carbon block is quite new and charged with air, it acts in the well-known way on organic matter, but after a day or two's soaking it is chemically perfectly inert, and in its cavernous depths and sinuous passages myriads of organisms are detained in darkness, at a favourable temperature and with passing food enough; and so they grow and multiply when the vase is empty, and are washed down when it is refilled, and the last stage of that water is very much worse than the first. He found that he must rebake the blocks every other day to make them of any use beyond that of tolerably fine sieves.

In the *Medical News* (Philadelphia, April 20-27) there is an elaborate paper by Dr. Charles Currier, of New York, on "The Efficacy of Filters, and Other Means Employed to Purify Drinking Water," in which he gives full details of the results of a long series of experiments conducted with great exactness on nearly every form of filter popularly and scientifically used. One is very common in the United States, which I have not seen: the Spiggot filter, a short cylinder of brass, which screws on to the tap, and is filled with fine sand retained by a perforated diaphragm at each end. It is generally regarded with much confidence, but is really absurdly useless. Dr. Curries found that the water passed just as fast from a given tap whether the cylinder were attached or not, and the idea of any filtration being effected under such conditions is preposterous. He found, as Dr. Viltchür had previously done, that every selective form of filter was only of temporary value in that respect; that, whatever the material might be, after a period of use varying from a few hours to three days, they excluded all gross impurities, but had no chemical action whatever upon the water; whilst, as for microbes, these either passed unchanged or—and this was most generally the case—they were increased enormously in number by cultivation within the pores of the filtering media.

Besides the ordinary forms, he experimented with Pasteur's cylinders of re-baked biscuit porcelain. The texture of these is so fine, and their continuity so perfect, that it might have been expected that they would have been free from every defect except slowness in action. It was found, however, that they failed as signally as the rest. At first not a bacillus passed, then a few was seen, and within two to five days they appeared in swarms in every cubic centimetre; whilst as the water passed only drop by drop, even under considerable pressure, the use of these expensive cylinders as practical filters was clearly out of the question.

We must not, of course, expect too much from any mechanical arrangement; and a filter which readily separates all foreign matters visible to the unaided eye, and leaves the water clear and bright, may be regarded, and with truth, as an appliance of some value; and so, if we stop there, well and good. We may be thankful, when muddy water only is at hand, that we have a means so simple for making it much less repulsive, and, to some extent, much less unwholesome. The fraud and deception come in when manufacturers sell filters which they warrant will not only strain but absolutely purify water—will render one polluted by sewage, for instance, safe and salutary as a beverage. This can only be done under certain exceptional circumstances, and for a very short time: a carbon block which is re-burnt or renewed every day can do it, but for that day only. If unchanged, it begins to fail on the second day, fails utterly on the third, and makes the water microbially worse than it was before filtration, and that, in an increasing degree, the longer it remains in use. And the dishonesty in selling a filter guaranteed to do what it is perfectly clear it cannot do, is made the worse by the false security it inspires in users who have not yet got over the unreasoning and blind faith which believes that whatever is printed must be true, and unquestionably true if two or three pseudo-scientific testimonials, from men who make a business of writing them, be appended. In the newspapers, in the advertisement sheets of medical and science journals, we constantly see statements in reference to filters, ludicrously untrue in fact, and of which it is hard to say, as of so many other trade announcements, which is the more extraordinary—the mendacity of the sellers or the credulity of the buyers.

The best of all filters, the simplest and cheapest, is a cone of unsized paper supported in a glass funnel. It involves a little trouble in using, but its economy—a hundred discs a foot in diameter can be bought for a shilling—compensates for that. And with these carbon can really be efficiently used as an absorbent and indirect oxidizer. Several weeks' supply can be re-burned, powdered, and preserved in full activity in a stoppered bottle, and a teaspoonful or so added to each new cone. The paper should be changed every, or at least every second, day, and the funnel should have a metal cover, and be washed frequently. It cannot exclude microbes, but it will certainly not lead to their multiplication. Half a gallon of water a day, enough for the drinking purposes of a tolerably-large family, could be prepared in this way by a filter of the size I have mentioned, and will come out bright and sparkling in the vase it is received in.

For cooking purposes the ordinary filtered water supplied by the companies is pure enough, the boiling which the act of cooking necessarily involves destroys the lethal activity of all organic matter contained in it; and there is no danger in using water—to take an extreme case—having the *materies morbi* even of enteric or scarlet fever mixed with it, if that water be thoroughly boiled for an hour or so, as it would be in the ordinary culinary operations of the kitchen. It is when such polluted water is used cold for the adulteration of milk, or, as has happened more than once, for simply washing the vessels it is collected or carried in, that danger or death ensues.

THERAPEUTICAL NOTES.

FROM OUR BERLIN CORRESPONDENT.

On the Use of Carbolic Acid—Eczema and Carbolic Acid—The Treatment of Erysipelas—The Therapeutic Effect of Codein—A New Dusting Powder—The Antiputrid Action of Fluoric Acid.

THE campaign against carbolic acid is now in full swing in Germany, as the number of carbolic acid poisoning cases is growing with such alarming rapidity that the question of Governmental interference is seriously ventilated. That carbolic acid should be obtainable from the chemist only on presentation of a doctor's prescription is one of the first measures which have been proposed. Professor Billroth, of Vienna, addresses himself to the public of Austria and Germany in warning against the use of carbolic acid, which is such a dangerous drug in the hands of laic people: not only is its internal use followed by most disastrous consequences, but even applied locally it may do great harm, as is proved by the frequent occurrence of carbol eczema. Any practitioner who has the opportunity to deal with these eczemas knows how difficult it often is to effect a complete cure. Dr. George Meger, of Berlin, publishes in the *Berlin Klinische Wochenschrift* a case of carbol eczema in a young man, who, during a stay in the country, got a contused wound of the third phalanx of the little finger. A surgeon stitched the wound. When seen by the author a few days afterwards he washed the wound out with 2% carbolic acid, dusted iodoform over it, and dressed it antiseptically. After a few days the skin surrounding the wound was found eczematous. Boracic acid vaseline was applied, which, however, did not stop the spreading of the eczema over three fingers and part of the volar and dorsal side of the hand. The author, on the advice of Professor Glulk, now applied lanolin, to which a little cocaine was added to stop itching. This treatment was followed by the most beneficial results; whilst a four weeks' course of application of boracic ointment had not advanced matters in any way, the effect of lanolin was already noticeable on the following day, as discharge and itching were considerably less. Four days afterwards the wound edges were formed by new epiderm, small patches of which were also visible within the wound; eight days after application of lanolin the whole large granulating surface was healed nearly completely. It must be said that the treatment with lanolin was combined with the internal administration of liquor arsenicalis Fowleri, but this remedy was discontinued after three days, and he attributes the excellent curative effect to lanolin only. The author therefore strongly recommends further experiments with lanolin dressing—pure, or combined with cocain—in all similar cases, but especially in fresh scalds and burns, where desquamation of the epidermic layer forms a prominent symptom. Lanolin will in such cases very appropriately substitute the old-fashioned mixture of lime water and linseed oil. In surgical chests, dressing cases, and ambulance conveyances, lanolin ought to find a permanent place, being the simplest and most convenient application in all cases of wounds, burns, etc.

When in Meyer's case of eczema the discontinuance of carbolic acid became urgent, he began to wash out the wound with an infusion of camomile, which, of course, had only a cleansing effect, but did not disinfect the wound. The latter, however, was unnecessary, because with lanolin aseptic healing was guaranteed, as Gottstein's researches have proved that lanolin is perfectly aseptic.

The favourable influence of salol in burns, communicated by Tato and Cabatelli, has probably also to be explained by the action of lanolin, with which the authors combined salol as a three per cent. ointment. The addition of salol or ichthyol to lanolin he thinks unnecessary for the said purposes.

Dr. Koch treated numerous cases of erysipelas with the following ointment:

Creolin	ʒ i.
Iodoform.....	ʒ iii.
Lanolin	℥ i.

This ointment is spread as an even smooth layer over the affected skin and its surrounding, on an area of at least two to three inches to the outside of the inflamed parts. The whole is covered by a piece of mackintosh. Dr. Koch selected creolin in the above prescription, because he thought that it was possessed of first-class disinfectant properties, without sharing the dangerous after-effects of carbolic acid. Iodine, which is derived from the decomposition of iodoform, stimulates absorption of inflammatory products. Lanolin has been chosen because it penetrates the skin best of all ointment bases.

The *Therapeutische Monatshefte* contains an article by Dr. Freund, of Strasburg, on the use of codein in diseases of women. The author was induced through the publications of Lauder-Brunton to try codein in gynæcological practice, and although not confirming everything what Lauder Brunton has stated, he nevertheless obtained favourable results. He gave it in abdominal pain produced by uterine and allied complaints, with very marked and rapid effect, especially if the pains started from the ovaries. The usual dose was followed—namely, half a grain three times a day in pills. In several cases the use of the drug was continued for months without any ill-effects arising.

Dr. Kiezer publishes an interesting paper on the use of salol as a dusting powder. He applied it in the following combination:

Salol	ʒ i.
Amylum powder	℥ i.

A varicose ulcer, in which all kinds of treatment had invariably been tried, was nearly completly cicatrised six weeks after the first application of salol. Six other cases of ulcerated leg were treated with the salol dusting powder; in all of them except one the success was equally marked, as in the first case. Excellent services were also rendered by the dusting powder in cases of sycosis, burns, scalds, wounds, defects of the skin, etc.

It is interesting to note what Dr. Gottbrecht publishes in the *Therapeutische Monatshefte* on the antiputrid action of fluoric acid. His researches were induced by communications on the use of fluoric acid in pulmonary consumption. He found that putrefaction of meat was prevented if it was kept in water which contained one per cent. of fluoric acid. Cultures of the bacilli of putrefaction were stopped in their growth if the nutrient gelatine contained from half to one per cent. of fluoric acid.

Reviews.

Abdominal Surgery. By J. Greig Smith, M.A., F.R.S.E. Second edition. London: Churchill. Bristol: Arrowsmith.

Works of this kind may be read now by the half dozen, scarcely yet by the whole dozen, but the volume before us, had it burst upon the world half a century ago, would have created an epoch in the history of surgery. Like many inventions and discoveries the art of abdominal surgery has crept on gradually; no individual operator can claim all its honour; but Mr. Greig Smith has contributed his full share to its advancement, both in detail and in principle; hence the present volume, as well as being a compendium of all that is known in every department of abdominal surgery, contains much matter which is not to be found elsewhere. A good example of the author's work is to be found in the thirteenth section, pages 625 to 676, on supra-pubic, or, as he says he prefers to call it "hypogastric" cystotomy, an operation which "is at present on the crest of the wave of popularity." Certain historical errors having been corrected, the author discusses with great lucidity the frozen sections of Garson and Petersen, and the comparative effect of vesical distension and the rectal pouch in elevating the peritoneal fold. He argues with apparent conclusiveness that general increase of the vesical dimensions, as by fluid injections, is the only thing which will lift that fold, but there is no reason whatever why rectal distension should increase the elevation, and if it does so at all it is only to an inappreciable extent. The one good thing which rectal distension will do, is push forward the posterior wall of the bladder, and bring it more within the operator's reach; but for every other purpose he is convinced that the contrivance is valueless, though not devoid of risk, except perhaps when a very thin rubber bag is used which will conform to the curves of the intestine without any tendency to burst the rectal wall. Very cogent are the author's reasons for distending both bladder and rectum by hydrostatic pressure, rather than by syringe or any form of hand-pressure. To force a given number of ounces of fluid into a bladder irrespective of its capacity or the tenacity of its walls, and then to imprison it there with an elastic cord compressing the urethra, sounds barbarously unscientific. One bladder may be full with ten ounces, while another is not full with fourteen, so that the amount of fluid injected, especially into a bladder which is diseased, is absolutely no criterion of how much it will safely bear; for the patient may strain violently, and the abdominal pressure be increased, or the bladder may suffer spasm and contract forcibly on its contents, to the great risk of vesical rupture. Wherefore, the author advocates the use of hydrostatic pressure through six feet of rubber tubing, connecting a catheter in the bladder, with a reservoir placed on a movable stand capable of ready elevation and depression, so that the fluid pressure in the bladder can be increased or diminished by merely moving the reservoir up and down. From a height of three feet the pressure exerted by water is about one pound to the square inch; the quantity of water requisite to produce that pressure in the bladder would be ruled by its distensibility, and would therefore be self-adjusting. Moreover, the pressure would be self-regulating; for should straining take place, or spasm of the bladder occur, there would be a refluent flow from the bladder out into the reservoir with so quick a relief of pressure as to make vesical rupture almost inconceivable. And when the spasm was over, the water would spontaneously run in again, and the distension be restored. This chapter of Mr. Greig Smith's may be read with interest by the most accomplished lithotomists, even by those whose experience and skill are such as to render his hints unnecessary to them.

Under the head of preparation of the patient, Mr. Greig Smith's considerateness for her feelings shews to especial advantage. The strong repugnance felt by some patients at the prospect of exposure during operation is known to those who have previous care of them, better perhaps than to the operating surgeon. When it comes to the point the patient will probably brace herself for the occasion; but it is the previous anticipation which causes the agony of natural, though foolish, modesty. The author's patients will be spared all this when they hear that, when he is the operator, they will be skilfully swathed from head to foot in warm blankets by careful nurses, and that there will be layers of warm cotton-wool over the chest under the flannel jacket, and rolls of warm wool around the limbs under the blankets; and that over all, completely covering the patient from chin to foot, and hanging down over the sides of the table, there will be a mackintosh sheet in which there has been cut a hole, "about seven inches long by four broad," directly over the area of operation, and that the margins of this hole are prepared like sticking plaster, so as to be closely adhered to the skin, isolating and leaving exposed only just so much of the abdominal walls as is necessary for operating. This passage (page 57) may be read with interest by operating surgeons, and communicated with advantage to nurses.

If the author's words are eloquent, so probably is his silence. We should like to have known his views on Apostoli's treatment of uterine fibroids by electrolysis; but his two allusions to it (pages 187 and 235) are short and cautious in the extreme. Unless his conversion be recent, like that of Dr. Keith, one would incline to the opinion that Mr. Greig Smith (speaking surgically) does not hold the Apostolic faith. And a subject which is at present so stormy may well be left alone. On another stormy matter, occasionally, but not advisedly called castration and spaying, the author speaks clearly (p. 169, *et seq.*) and with discretion. To lose what is lost by the operation in question may not be pleasant. Neither is it pleasant to lose an eye or a hand, yet all three losses are occasionally necessary. The surgeon who relieves his patient by removing a diseased eye may still do so without ruining his reputation; but if he similarly relieves a patient by removing her equally diseased "appendages," he may raise a storm of popular sentiment which will not improbably make shipwreck of him.

All the details of his art are given in one or other of the author's nearly 800 pages. As a sample of his care in details we may indicate that ligatures, knots, and sutures are described and figured whenever there is any chance of difficulty. At

page 138 the Staffordshire knot is engraved and described, and honourably designated "Lawson Tait's" after the name of its introducer. It is a sub-variety of the clove-hitch which is one of the most useful knots in existence. The intestinal suture given in figure 64 seems indistinguishable from Mr. Erichsen's second method of constricting a nævus [*Sc. and Art of Surg.*, ed. 5, vol. 1, p. 652] applied to the *interior* of an intestine. It is slow, difficult, and demands so much of the manipulative pawing and teazing which all enterorrhaphists deprecate, that the author's notice of it, though very courteous, is such that no one will think of using the suture while he can avail of the far better one shewn on the 473rd page.

If pages 2, 3, and 4 did not occur on the very threshold of the book where they are calculated to produce a bad first impression on the mind of the reader, they might be passed over in silence. It is necessary to say that they are not a sample whereby to judge of the rest. Almost all the misprints, as "latterally," "vetebral," "orfices," are collected there; the line bb' is by no means "at the highest point of the crest of the ilium," and if "a portion of the descending colon" (? the splenic flexure) be in the left hypochondriac region, why has not M. Tillaux drawn it there? The rest of the book will be read with pleasure, even by surgeons who never perform an abdominal section.

R. Augustine Chudleigh, M.A.

The Vivisection Controversy in Parliament: an answer to a speech delivered by the Right Hon. Sir Lyon Playfair, M.P., etc., in the House of Commons, April 4th, 1883. By Surgeon-General C. A. Gordon, M.D., C.B., etc. London: Williams and Norgate. pp. 95. 1888.

We have in this essay by Dr. Gordon the "last word" upon the anti-vivisection controversy; not that we doubt the possibility of more "last words" before we arrive at the conclusion—*probatum est*—Q.E.D. Regarding the question at issue from his own point of view, the object of the author is to "demonstrate that the arguments adduced in opposition to the Bill, proposed by Mr. Reid, were not only unsupported, but directly negatived by the weight of published evidence; that the grounds of utility and of humanity on which the rejection of that Bill was desired by advocates of 'experiment' on living animals are fallacious in themselves, and the practices thus indicated, in all respects, deserving of condemnation." With this object before him, the method adopted in the arrangement of his comments by Dr. Gordon is as follows, as stated in the the author's "introductory remarks:"—"The speech delivered by the Right Hon. Sir Lyon Playfair being looked upon as having led to the insuccess of the Bill introduced by Dr. Reid, I have taken from the published record of the former particular paragraphs containing definite statements; I have arranged them consecutively as they occur in that record, and in reference to each have made such comments as I have been led to by the study of records and works to which I had access." In his introductory remarks the author expresses the conviction that the evidence thus brought together is adverse to the grounds therein stated in support of the practices allowed, *i.e.*, to vivisection under any form or conditions whatever.

Sir Lyon Playfair, in opposing the views of the anti-vivisectionists as expounded in the Bill introduced into the House of Commons by Dr. Reid, stated the proposition that under the proposed legislation "a man could not stroke the back of a cat to show a student that electricity was developed without committing a crime; that he could not give a constipated patient a dose of castor oil as an experiment to see whether he could do without a drastic dose of croton oil; a physiologist could not put the web of a living frog under a microscope to show the circulation of the blood." Dr. Gordon's comment hereon is that it is in accordance with medical usage, ethics, and morals, and with the demand of the public, that in conducting the treatment of any particular case, a medical man may modify and change his methods and means to such an extent, and in such a measure as from past experience, and a due exercise of his judgment, seem to him to be necessary." In making this admission he urges that this is not saying that medical men have a right to experiment vaguely, and for no particular end upon their patients. Further, the author expressed a doubt whether a medical man in doing so would not place himself within the reach of legal proceedings.

Alluding to the general subject of "experiments," Dr. Gordon has the following remarks which we venture to doubt being justified by facts:—"In perusing evidence adduced by the 'experimentors,' the thing which most impresses one is the little importance the physiologists attach to pain, and their general incredulity that their experiments cause any, or if any, that is serious. We find vivisections described of absolutely sickening horror, which suggest agony such as the imagination cannot realize; and yet the physiologists who perform them inform us that in reality the suffering of the animal was quite insignificant; the pain endured only of the more trivial sort." Modern physiologists, the author insinuates, regard living animals, with Descartes, to be but animated machines. This picture admits of some little deduction for accuracy. Do not the exertions of physiologists in the direction of obtaining anæsthetics rather tend to dispose of a large proportion of these animadversions, which of themselves we cannot believe to be justified, and which are not borne out by the reports of Goverment inspectors?

In the opinion of the opponents of vivisection there are other methods of research which have stronger claims upon our regard than the results of experiments upon living animals; these are clinical and pathological investigations, and morbid anatomy and physiology. The results of such observations, aided by microscopy, are undeniably of the greatest value, but they do not exclude the collateral help of the conclusions to be derived from experimental research. Sir Lyon Playfair expresses what we are disposed to regard as an incontroversible proposition:—"By experiments on animals, medicine has learned the benefits, and also how to avoid the dangers of many potent drugs, as chloroform, chloral, and morphia." Dr. Gordon, however, does not accept this statement, quoting Mr. Tait as his authority for looking "upon all new drugs with great suspicion, and for fearing that most new drugs do more harm than good." "Chloral most certainly has done so. . . . Carbolic acid has done more harm than good." These statements, we take leave to say, are directly opposed to our own experience, and we feel confident that we are not alone in regarding them as anything rather than a temperate and deliberate, or scientific conclusion. Having carefully gone through Dr. Gordon's comments upon Sir Lyon Playfair's propositions, we cannot otherwise than concur in the opinion, that the "proposed Bill originated in a benevolence wholly indiscriminate, and

that it will infinitely augment the animal suffering it ignorantly seeks to alleviate;" inasmnch as it will diminish the prospect of discovery of the means of relieving or preventing suffering; nevertheless, we concede that Dr. Gordon has made out a strong case for the anti-vivisectionists.

W. B. KESTEVEN, M.D.

Short Notices.

Case of Myxodema. By Dr. MOSLER. *(Bericht über die verhandlunger der deutschen Gesellschaft für Chirurgic xviii. Kongress*, 1889.)

THE patient was a female, æt. fifty-six years, who had suffered severely from coldness of the feet; gradually she found that the thumb of her left hand became paralysed, in the course of three months she noticed swelling of the back of the left hand and of the fingers, and subsequently of the whole arm. In two years time the swelling of the surface had extended to the trunk and right upper extremity, and subsequently the lower extremities appeared to be œdematous. When this had reached to a considerable extent, the face and eyelids were swollen. About the same time the mucous membrane of the mouth, nostrils, and pharynx were attacked by the affection. Speech was impeded, the voice hoarse, swallowing was rendered difficult. Associated with these symptoms was weakness of the memory, and other nervous symptoms, aggravated by the cessation of menstruation. These changes depended upon the deposit of a mucoid serum beneath the cutis and mucous membranes. The movements of the hands and feet became difficult; the skin was hyper sensitive to pressure; motor or sensitive paralysis was not perceptible, but there were disturbances of the vaso motor functions. The patient became apathetic and had a stupid aspect. No distinct lesion of the thyroid body could be detected, the thickened state of the integuments prevented a close investigation of that gland, but a notable pad of fatty tissue filled up the space below the chin. The examination of a portion of integument from the neck showed œdema and proliferation of cells of the smaller arteries. The urine exhibited was of light specific gravity, but exhibited no special pathological conditions. In this case there is a morbid condition *sui generis*, analogous to the results seen after the extirpation of the thyroid body. Dr. Mosler quotes known authorities upon myxœdema, and submits the preceding as a typical case of that affection.

W. B. KESTEVEN, M.D.

A Guide to the Alterations in the British Pharmacopœia (1885), comprising an Epitome of the Changes, and an account of the New Preparations, their Character, Uses, Doses, and Modes of Administration, together with a Therapeutical Commentary. By PROSSER JAMES, M.D. Third edition. London: Churchill.

THERE is a very long title to this small book, but, happily, it fully carries out in detail what is implied in the title—something that cannot always be said of books, that promise much and perform little. At the revision of the new Pharmacopœia, new medicines were incorporated, and it is to these medicines that Dr. Prosser James desires to direct attention. Thus we have a very excellent account of such substances as eucalyptus, pinus sylvestris, sandal wood, menthol, thymol, caffeine, coca, jaborandi, etc. In the article on cascara sagrada, he makes a very strong comment. He says that "it is a marvellous thing that the General Council of Medical Education translate this as 'sacred bark.' Such a popular name may be very well as a synonym, but is certainly no rendering of the Latin words. But surely the learned Pharmacopœia Committee should know that 'cascara sagrada' is not even dog Latin for sacred bark, and yet they proceed innocently to decline it after the first declension feminine, and give us both words in the genitive. So we must write ext. cascaræ sagradæ, etc., though the words are not to be found in Ainsworth or Riddle, but will turn up in the first Spanish dictionary which may be within reach of our Educational Council. It was scarcely to be expected that a committee on which Oxford is so ably represented should show weak Latinity, but even Homer is said to sometimes nod, and the ext. cascaræ sagradæ of the new British Pharmacopœia may serve to raise a smile, and remind us of the Oleum Theobromæ of 1867." We shall have to accept this nomenclature and declension. It is but adding another item to the quantity of bad Latin we already possess. Dr. Prosser James' little book has evidently been appreciated, as it has reached a third edition. The present one has been much improved. One of its best features is the index.

Dermoids, or Tumours containing Skin, Hair, Teeth, etc. By J. BLAND SUTTON, F.R.C.S., etc. London: Baillière, Tindall & Cox.

THIS book is the outcome of the Hunterian lectures, delivered at the Royal College of Surgeon, London, in 1889; and in the new form they have gained, as in addition to the text, there are admirable illustrations of the structures under consideration. Dermoid cysts are now studied in a manner unknown to the older pathologists, as the evolutionary theory has materially helped to clear up their pathogenesis; and Mr. Sutton has so studied his subject that we have in this treatise a key to the explanation of those abnormal tumours, which have so long puzzled pathologists. Dermoids, according to Mr. Sutton, are cysts or tumours furnished with skin or mucous membrane (which may or may not be accompanied with the appendages peculiar to these structures) occurring in situations where skin and mucous membrane are not normally found. This definition is sufficiently comprehensive, and Mr. Sutton then considers in detail a number of specimens which have been furnished him by the pathological, obstetrical, and gynæcological societies, and by individual workers, as Mr. Henry Morris and Dr. Granville Bantock. Dr. Granville Bantock furnished him with a very interesting specimen of a mamma from an ovarian dermoid, and here we see the bearing of Mr. Sutton's studies from the evolutionary point of view. Another interesting chapter is that on bronchial cysts; it is an excellent model of close reasoning applied to science. The book only extends to 131 pages, but it has matter in it for a few weeks' reading.

What to do in Cases of Poisoning. By WILLIAM MURRELL, M.D., F.R.C.P. Sixth edition. London: H. K. Lewis.

"I AM told," says Dr. Murrell, in the preface to the fifth edition, "that this book has been the means of saving many lives. I hear that a gentleman who thought of poisoning himself changed his mind on reading the directions for treatment. He was of a retiring disposition, and objected

to have a pint of hot strong coffee injected into his rectum." General readers, as a rule, will not take much interest in this book; would-be suicides, if they consulted it, might certainly be deterred by the fulness with which directions for treatment are given, and the rigor of the treatment. For the practitioner and student the book is invaluable. It should lie in a poison-bag or case ready to hand, so that in emergency it may be consulted. Memory is not always to be depended on, besides we have so heavy a tax on it that it is no wonder we forget so much. Nay, it is perhaps a blessing that we can forget, or do forget, for otherwise there would be no progress. This may sound paradoxical, but on examination it will be found not far from the truth. Dr. Murrell has even included a consideration of an antidote against many other ills of life—the fee—which is very often forgotten, so that the practical nature of his work, and his consideration for the patient in relieving him or his friends of the trouble of fixing it, are deserving of the highest praise.

Anæsthetics, Ancient and Modern; their Physiological Action, Therapeutic Use, and Mode of Administration, together with an Historical Resumé of the Introduction of Modern Anæsthetics—Nitrous Oxide, Ether, Chloroform, and Cocaine—and also an Account of the more celebrated Anæsthetics in use from the Earliest Time to the Discovery of Nitrous Oxide. By George Foy, F.R.C.S. London: Baillière, Tindall, & Cox.

This is a most interesting book, and we thoroughly sympathize with one of the author's aims when he says, "In undertaking the work I was actuated by the wish not to rob the moderns of those things which they have discovered or judiciously followed, but to render up those inventions which have been described by the ancients to their rightful owners." It will be found by referring to Mr. Foy's book that the prevention of pain by means of drugs is not a modern conception or practice. The earliest writers on medicine appear to have been acquainted with medicines which had the property of producing insensibility, and we refer our readers to the very interesting and learned account given by the author of the practice of the ancients in this respect. The history of the discovery of chloroform is one of the romances of modern times, and its recital even can always be invested with fresh interest. Mr. Foy has not only made the chapters devoted to the subject interesting, but he has treated it on strictly scientific lines. The deaths from chloroform in modern times have been alarming, if we can credit certain statistics. According to some it is fixed at 1 in 525 administrations. This is a very serious mortality, and we do not wonder at its exciting comment and the recourse to other agents. The old statistics did not give such results. Dr. Hunter McGuire had 28,000 administrations without a single death; Dr. Chisholm had 10,000 without a single death; Kidd (London), 10,000 without a death; Bardeleben administered chloroform 30,000 times before he had a death; Billroth 12,000 times before he met with his first accident, etc. These figures are remarkable, and cannot be explained away. In looking into the causation of the high death-rate we have to look at two separate factors: (1) the administrator, and (2) the chloroform. It ought not to be difficult to explain the high death-rate. Dr. Foy's book will, we believe, be widely read, and will help in the clearing up of this very important point, because it will set men thinking, and that is one of the first steps required, for then, as Mr. Foy says in his preface, "Truth will come out." This is a book to be taken up as a relaxation from professional labour, and we heartily welcome it to our shelves.

Heredity: a Study, with Special Reference to Disease. By R. A. Douglas Lithgow, LL.D., M.R.C.P., etc. London: Baillière, Tindall, & Cox.

The readers of the Provincial Medical Journal have been able to form an opinion on this book, as most of the material in it appeared in the columns of this journal. From many letters received we have every reason to believe that the articles were much appreciated, and now that they are presented in a collected form to a wider circle, they are more likely to be still better appreciated. Dr. Lithgow has brought to his studies a liking for his subject, and this is evident in the painstaking manner in which he has followed the track of heredity through all its different manifestations, and he certainly deserves the credit for presenting many of its phases in a new light, and giving to the study of heredity in disease a systematic basis. By means of the admirably classified and extensive index, the reader can at once find out the range of heredity. This index is all the more necessary, because Dr. Lithgow has not divided his book into chapters, but has rather treated it after the manner of an essay, putting headlines, however, for the various subdivisions of his subject. Heredity is one of the most interesting subjects in connection with medicine, and of late years greater attention has been deservedly given to its influence, and English literature has had the reproach of being particularly barren in all that relates to this complex problem—a reproach which has of late years been very considerably diminished; and amongst the latest contributions, the work of Dr. Lithgow will be accorded a high place.

Man and his Maladies, or the Way to Health: a popular Hand-book of Physiology and Domestic Medicine in accord with the Advance in Medical Science. By A. E. Bridger, B.A., M.D., B.Sc., etc. London: John Hogg.

Dr. Bridger has evidently a high conception of the intelligence of popular readers, or he would not have presented them with this philosophic work, and we sincerely hope that he will find an audience of readers; for whoever can master the principles of life and the principles of scientific medicine, as laid down by the author, will certainly not venture to treat himself; but with a higher conception of the wonderful structure of his body, wisely seek a physician, and even be particular as to the one he consults. Certainly, mothers will not think of treating their children when suffering from infantile complaints if they read his descriptions. We give one example: his remarks on whooping-cough. He says very truly: "The frequent repetition of a violent cough, such as is that of whooping-cough, constitutes in itself a grave danger. The strain thrown by it on the blood-vessels of the head is visible in the swollen and bulged face, the blood-shot eyes, and the not unfrequent bleeding from the nose. These are of trifling import, but the pressure on the circulation in the brain is of a serious kind, and

may even end in an effusion into the ventricles of that organ, and this to convulsions and death—a by no means uncommon termination of the disease. The violence done to the lungs may also end in severe secondary mischief, of which *bronchitis, chronic dilatation of the bronchial tubes* (*i.e., bronchiectasis*) or of the air vessels (*i.e., pulmonary emphysema*), or obstruction of some one or more of the bronchial tubes, leading to *collapse of a portion of the lung*, are perhaps the commonest; whilst pleurisy and the capillary variety of bronchitis, both very formidable complications, may also be occasioned." The italics are Dr. Bridger's. The author may certainly take credit for not producing a book framed upon the ordinary conception of the complete pocket physician, so many of which are now in the market. We cannot help thinking that his book will never become popular, though it may have the effect of making the author popular.

On Bedside Urine Testing: a Clinical Guide to the Observation of Urine in the course of work. Fourth edition. By George Oliver, M.D. Lond., F.R.C.P. London: H. K. Lewis, 136, Gower-street.

Dr. Oliver, by the introduction of his tests, has not only simplified our methods of urine testing, but he has almost revolutionised them. They are admittedly most convenient, portable, staple, trustworthy, cleanly, handy, and time-saving. In this book, which has now reached a fourth edition—a proof of its need and popularity—Dr. Oliver explains how and why the tests should be used; and he has pointed out the diagnostic significance of the various urinary states usually met with. Urine testing has now resolved itself into something more than testing for albumen, and the perfunctory mode of examination once in vogue has disappeared. The advantage of knowing the condition of the urine is fully appreciated by all sound practitioners, so that we need not insist upon the great value of a guide of this nature, which embraces nearly all that can be said on the subject.

Buxton: its Baths and Climate. By Samuel Hyde, L.R.C.P., M.R.C.S.

This is a guide to the baths and waters of Buxton, giving an account of the origin of the place, the nature and therapeutic value of the treatment received there, an exposition of the principles of bathing, and of massage, with a description of the walks and drives in the neighbourhood to Buxton, likely to prove useful to an intending visitor, or of the physician who desires to know what kind of case is likely to benefit by residence there. The author discusses the subject of absorption by the skin, and advocates the use of a highly rectified spirit to remove the fat from the surface of the skin before employing the bath. Now, considering the tension of gases and fluids in the blood vessels, we much doubt whether the obstacle to absorption lies in the fat alone; apart from this we question the advisability of removing from the whole surface of the body so valuable a protective as its natural fat. We are not disposed to agree entirely with the author in his condemnation of warm climates for all cases of phthisis; a certain number of patients are certainly benefited by a cold bracing atmosphere, but there are others who cannot stand cold, who are just as certainly relieved by warm surroundings; probably an increased knowledge in the future will help us to decide the kind of case suited to each kind of climate. Again we are disposed to question the soundness of the view that a place is healthy in proportion to the scantiness of its vegetable; a region without plants and wild flowers, as Buxton is claimed to be, will hardly recommend itself as the best place for an invalid with much time on his hands.

W. T. Holmes Spicer, F.R.C.S.

Cancer and its Complications. By C. E. Jennings, F.R.C.S., M.S., M.B.

The preface states that this book was written to elucidate certain points in our knowledge of cancer, the main one being that cancer is a local disease, and that, therefore, if removed sufficiently early, it can be cured. Including under the term cancer the carcinomata and sarcomata, the author gives all the varieties of each group, with a brief description. This is followed by an abstract of the great discussion at the Pathological Society in 1874 on the nature of cancer, some of the opinions then stated being given at some length. The author has little difficulty in showing that the greater strength of argument is in favour of the local origin of cancer, although there may be a disposition in some tissues favourable to its onset and growth. From this there follows the inference that cancers may be completely eradicated by surgical methods if taken early enough. The next part of the book is given up to the diagnosis and treatment of cancer as it occurs in the various regions of the body, with the operations best suited for its removal. The author asks us not to give up the hope that some specific may be discovered, which will exert an influence on the growth of cancer; he himself states his belief in some beneficial action of Chian turpentine when given in large doses for a sufficiently long time. Certainly there is no objection to its use in cases which are beyond operative treatment, but we quite agree with Mr. Jennings, in not having sufficient confidence in it to advise its use to the exclusion of surgical measures, in cases where the cancerous growths can be completely eradicated.

W. T. Holmes Spicer, F.R.C.S.

London, Ancient and Modern, from the Sanitary and Medical point of view. By G. V. Poore, M.D., etc. London: Cassell & Company.

This book is an expansion by two addresses delivered by the author. It is a book to take up in a leisure moment, as it is written in a light and pleasant style, and abounds in anecdotes and short histories of old medical worthies. The history of the chief London hospitals is well given. The book is illustrated by a map, showing London in 1658. It has several illustrations of well-known medical places of interest.

The Provincial Medical Journal,

NOVEMBER, 1889.

Amongst the many congresses held this year there was one of seamen, and Cardiff was the locality selected for its sittings. The enormous interest connected with the shipping industry is out of all proportion with the very slight interest taken in those who "go down to the sea in ships." The hardships of the sailor's life, independent of the dangers, are proverbial. But the sailor, in health, appears to make little of his work or its perils. He cannot be considered to be a grumbler, or we hardly think he would so long have submitted to many of the conditions of service and to his surroundings. The sailor does not expect to lie in a feather bed, or to have on board ship a spacious apartment to sleep in; but he certainly does appear to have a claim to a full supply of fresh air in his habitation on the forecastle. The convict in prison is entitled to 300 cubic feet of air, but the sailor has to be content with seventy cubic feet space, a quantity totally insufficient for any human being. The food, too, served to the sailor in some vessels, is of the worst description, and as hard work has to be done in all weathers it appears a very short-sighted policy to under-feed their crews. There may be some difficulties in connection with the sleeping accommodation in the cabins of the men, but there ought not to be the slightest difficulty in connection with the food supply. This is a matter which concerns the men themselves, and which they can easily settle, as they seem disposed to do, by combination. There is one subject which appears to us to demand more serious attention than it has received from the Legislature, and which more nearly concerns us—viz., "The Medical Care of Sailors." The policy of the best steamship companies is to have an experienced surgeon who makes a speciality of this branch of work; but, unfortunately, all the companies do not adopt this system—not because they cannot meet with experienced men, but because they will not offer sufficient inducement for competent men to take up their appointments. The principle of supply and demand is acted upon. They find that they can obtain medical service at a cheap rate in the open market, and as there are a number of candidates who want to see a little life, or a change, they fill up their appointments from candidates who do not intend to settle down to a seafaring life. The surgeon with certain companies is looked upon as a supernumerary—as something necessary to comply with the law, but as a nuisance rather than a help. He may make himself disagreeable by pointing out sanitary defects, or by exposing the bad dietary of the men, and he may add to expense by insisting on proper hospital accommodation.

The commercial element has a very large preponderance with some shipping firms, the lives and comfort of the men being a secondary consideration. Our remarks do not apply to a number of companies who recognise that their seamen are deserving of full consideration, and that their best interests are consulted by making the best possible provision for their men. The paper read by Dr. Leet at the Seamen's Congress at Cardiff exposed some of the legitimate grievances of sailors in connection with the medical service, and it is significant of an awakening interest on the part of the sailors themselves that a paper of this kind should have been read at this conference; though we are astonished that there was not a discussion upon it, and that some further testimony was not adduced as to the ill-condition of the hospital accommodation on board the ocean-going steamers. And this is very remarkable in the addresses of the various speakers: they dilated on the hardness of the sailors' life; they described his sufferings in case of wreck, etc.; they spoke of his services to the nation; and then they went on to his grievances, and exposed the heartlessness of those who sent coffins to sea in place of ships, and overloaded vessels, but none of the speakers touched upon the subject of medical aid. This omission may be taken to negative the statements of some of the ship surgeons, who have written so strongly upon the bad accommodation provided for sick sailors, and upon the slight consideration given by ship owners to the medical treatment of their crews. But when examined, it does not admit of this conclusion. It took the profession a long time to excite public interest in the medical treatment of the sick poor, and even to stir up the public as to the value of sanitation, but we did succeed, with results known to all our readers. There is a process of evolution running through everything. The germ must be sown, and in time it grows, but it requires favourable circumstances for its development; so we may reasonably expect that history will repeat itself with regard to the medical provision for sailors, and that

> "The dear little cherub that sits up aloft,
> To watch o'er the fate of poor Jack,"

may put it into the minds of the leaders of the Sailors' Congress to give a little more practical assistance to the schemes brought forward for the better medical care of our seamen.

Longfellow, in a well-known poem, represents a youth climbing the Alpine heights with a banner, on which was engraved the word "Excelsior," and higher the youth went—but his end was early death. The spirit of the poem is admirable; we should aim at the highest ideals, even though the end be death. And in medicine it is well to start in life with the loftiest ambition, with the highest conception of medicine, both as an art and a science. The roseate pictures drawn by the introductory lecturers help the youth to form in his own mind a loftier ideal; and it may serve as an incitement during life to keep the motto "Excelsior" before his mind. The conception of medicine is of two kinds: First, the higher one as a beneficent profession, practised in the interest of humanity, the great object in view being the relief of human suffering which may be achieved in various ways by medicine and by surgery. The historical aspect of this question is most attractive; through

all the ages we find the physician taking the part of the good Samaritan, not only pouring oil into his wounds, but carrying the patient upon his ass. The traditions of medicine have been carried down in unbroken succession, and appear likely to be carried down until MACAULAY'S New Zealander comes to stand upon a broken arch of Westminster Bridge to sketch the ruins of St. Thomas's Hospital. The second conception is of a more material nature, and relates to the pecuniary results which may follow from the practice of the art. The potentialities are great. Visions may arise before the mind of the student of the fabulous incomes supposed to be made by fashionable west-end physicians and surgeons. The surroundings of wealth are very often mistaken for wealth itself, for "all is not gold that glitters;" and so the average conception of the income of the successful practitioner is magnified by the glamour of youth. The prospect is very luring. A house in Harley-street or Cavendish-square, with a country residence down some of the reaches of the Thames, a magnificent equipage to drive round and visit aristocratic patients, a daily list of which is kept by a gentleman's gentleman, who assures each new-comer that it is only by special appointment, and by special favour, that the doctor can be seen, as he ostentatiously flourishes his carefully prepared list of the fortunate individuals who have been able to obtain a consultation. These are but a few of the convincing proofs of success upon which we might indefinitely expand. Each French soldier is said to carry figuratively, in his knapsack, the baton of a Marshal of France, so each student at the introductory lecture may also be said to have within himself the potentiality of becoming a leader in medicine, with all the rich rewards of such a position. This is the ideal. What though a youthful romance be built up of the future, which, like a house of cards, tumbles to pieces at the first rude touch; yet there has been a pleasure in the construction of the edifice, just as with children there is said to be as much pleasure in the destruction, as in the erection of the house of cards. Our life is very much made up of broken idols. Most of us are day-dreamers, for without the imaginative faculty man would be a very poor creature. TENNYSON has said that—

> "It's better to have loved and lost
> Than never to have loved at all."

And so it is better for the youth to have at one time had ambition, than never to have been stirred by noble influences. The romance of life has a very short period of existence, and the halcyon days of studentship are the days, for after qualification, the stern necessities of life, and the struggle for existence, put a rude end to all romance, and the question comes as to how practice should be commenced, and where, and when? This question is becoming more difficult of solution each day, For every hospital appointment at our schools of medicine there are too many candidates; for the public service there are too many candidates. Private practice does not present so many openings, and here the competition is so fierce that every form of bidding for patients is resorted to, so that the youth who hopes to receive guinea fees has perforce to content himself with the odd shilling, which time immemorial has consecrated as the medical fee. What a falling off is there, to have to accept the ignoble silver in place of the nobler metal. And then, too, the surroundings under which even this small sum has to be earned. It has to be won in a district far removed from Mayfair, and amidst an environment all too unlovely, and from clients whose dress and *entourage* are very different indeed from those who flock the crowded consulting rooms of West End physicians.

Facilis descensus averni; and it is fortunate perhaps that the transition is brought about with apparently so little friction, and that men so easily accustomed themselves to their circumstances, otherwise it would be impossible to have the profession in such a state as it is now, for we cannot imagine it possible that the benches of our lecture rooms would be filled with students who looked forward to the practice of medicine under such conditions as are at present the fashion. They must enter the profession surely with richer anticipations than is conveyed by the prospect of a provident dispensary, or a shilling practice, and their idols must have been framed after the model of the consultants and specialists whose lectures they attend. It may be true that the nobility of the profession, and the fact that they are relieving humanity, contents them even in the humblest quarters; and if this be so, then indeed does the profession deserve well of mankind. In any case it is consoling to know that philosophy enters so largely into the medical nature, and that when men find they cannot reach the top they are content to linger at the bottom. An American humorist said "there was no use in crying over spilt milk, as it only made the rest more watery;" and so if the student repined instead of setting to work in another sphere, the condition would be even still worse, we may come to the cardinal conclusion "that all is for best in the best of all possible worlds."

THE word euthanasia frequently occurs in modern literature, and when we come to consider its real meaning, or its root, we find that it has its origin in the Greek *eu thanatos*, or a happy death. It has been applied by the poet to those who found a harbour of rest after the fierce battle of life, but it has another meaning: it is a euphemism for self-homicide, or suicide, and judging by our modern records it would unfortunately appear that this form of escape from the troubles of the world is on the increase. If death were the end of all, and we had simply "to die and lie in cold obstruction and to rot," then, indeed, the term would be applicable; but SHAKESPEARE adds a few very important words to the above quotation which altogether alter our estimation of euthanasia. He says in "Measure for Measure:" "Aye, but to die and go we know not where." This view of the possibility of a hereafter (which to most of us is a certainty) opens a vein of thought as to the causes which are at work in the production of suicide in modern

times. We trust that we are not about to have a Pagan renaissance, or that suicide is to be elevated into a moral virtue, as believed in by a number of eminent Pagan writers. If belief in a future state should become extinct, we fail to see what check we shall have upon those who have become tired of existence, for life to a large number is anything but a pleasure, and life to those who are suffering from incurable disease is a burden. At present, for the many "it is nobler for the mind to suffer the sting and arrow of outrageous fortune," and to bear disease, because they are consoled by a rich promise held out by God; but if we take that hope away, there can be nothing to keep them from cutting the knot in a summary way. Self-homicide, however dignified by the term euthanasia, is opposed to Christian ethics, and it is not only so opposed, but it is punishable by law. *Felo de se* is a statutable crime, and the property of the suicide, we believe, really reverts to the Crown. By another euphemism the crime is condoned, as we find appended to the verdicts of juries in case of suicide the legend "Temporary Insanity," this being done to spare the feelings of relatives, and to save the property of the unfortunate who has taken his own life. It is a question open to very grave consideration whether this euphemism is beneficial to society, and whether we are not encouraging self-homicide by being so tender about it. Undoubtedly, insanity does lead to self-destruction, but it cannot be seriously entertained that every suicide is insane.

The increase in suicide is all the more remarkable, as it is coincident with the spread of education, for, *primâ facie*, it might be thought that education would rather tend to prevent this crime; but when we actually find that suicide prevails even amongst children, we can see that knowledge is not always power, and that pure learning is not of itself a preventive of crime. There must be many causes at work in the production of the crime, and some are at once apparent. We know positively that drink causes a certain percentage; that insanity also adds a percentage; but besides these two causes there must be others at work, for both of the former do not account for even 50 per cent. of the suicides. Over-excitement, fierce competition, the wear and tear of modern life, disappointment, passion, and many other similar causes help to swell the annual average; but these by themselves ought not to be sufficiently potent causative agents, if there were any sense of moral obligation in the individuals, or if they had a solid substratum of religious belief to fall back upon. It is a difficult problem to solve as to the why, though we may moralize upon it, and suggest a train of thought in some of our readers' minds which may help more thoroughly to localise the lesion. The modern literature of the day has often been incriminated. "*Is life worth living?*" asks one writer. Immediately we have a flood of answers of the most pessimistic kind, and some poor weak mortal—influenced in a measure by the gloomy picture drawn—cuts the thread, and seeks release from the troubles of life in what has been called "a happy death"—euthanasia. We can point to many other books which more or less—far from the intention of the authors—contribute to despondent views of life, and indirectly lead to suicide. The hopeless views of life, the blotting-out of a hereafter and an eternity, the sceptism prevailing as to the value of religion, are not indications of a healthy state of society; but, fortunately, all our literature is not painted with the same cast, and we fancy we see a lifting of the cloud, and signs of a more optimistic revival. Mrs. Henry Wood, in an article published in the *Argosy*, has very graphically described the feeling of a would-be suicide. He intended to commit the act, but nature cast upon his soul the sleep of exhaustion, and in a dream he passed through all the horrors of an eternity. Remorse stirred his heart, yet he could not escape, and he awoke in agony, never more to dream of self-homicide. This man was sorely tempted, and he hoped to escape from his misfortunes by tasting the quiet of the grave, "but there was no quiet for the suicide." It is a powerful piece of writing, and Mrs. Wood has grasped the great truth that despair should not so grasp the human heart that God's compassion may not reach it.

The influence of writers who hold that suicide is a crime ought to be as great as that of those who condone it as an offence against the Deity and the moral law, and we believe that the Christian moralists are more numerous than the apologists for euthanasia. The influence of our profession has always been on the theistic and Christian side, and we believe that the number of suicides has been much diminished by the personal influence of medical men.

At the recent Congress of French Surgeons the subject of the immediate and remote results of operations for local tuberculosis was examined by a number of eminent operators, as MM. Verneuil, Lannelongue, Le Dentu, Guyon, Terrillon, Boeckel, etc., who considered it, as it affected the special parts of the body, as the fungus, bladder, foot, ovary, eye, etc. M. Leon Petit (*L'Union Médicale*, Oct. 5th, 1889) has ably summarised the facts brought out by the discussion. Surgical tubercular lesions—caries of bone, articular fungosities, scrofulous adenitis, spina ventosa, cutaneous ulcerations, etc.—are due to the presence of tubercular elements, and contain the bacillus of Koch. For some time—and in particular since the nature of the tubercular lesion has been known—there has been a constant strife between operative medicine and therapeutical medicine as to the treatment of the local lesions. To solve the question we want facts, and not reasoning. We must classify the facts collected into numerous divisions, on account of the multiplicity and diversity of the elements of appreciation, and we must follow the cases for a number of years. It is only thus we can appreciate the immediate and remote effects of operation. The difficulty arises of our being unable to follow the after-history, as the patients are lost sight of. The immediate results may be good, mediocre, null, or bad. It has been said that with antiseptic dressing there are no complications with operations on the tuberculosis; that numerous facts testify that the operation may give start to

lesions and to tubercular lesions, in organs remote from the operative zone—lungs, meninges, liver, kidneys—and provoke the rapid development of these lesions. A patient suffering from tubercular arthritis of the knee: on auscultation, nothing is found the matter with his lungs, and amputation is performed. Two days afterwards pulmonary complications take place, and the patient dies within the week. At the autopsy both lungs are found full of miliary tubercle. During and after operation the presence of tubercles in the lungs constitute a constant danger of asphyxia, and the patient is anæsthetised. Many cases of syncope—mortal or not—met with during or after anæsthesia are due to the existence of miliary tubercle of the lungs, which is often impossible to discover by auscultation, and only reveals itself by *post-mortem*. MOLLIERE, of Lyons, advises when there is phthisis in the third degree rapid operation, in order that the quantity of ether or chloroform may be reduced to a minimum. The traumatic accidents consecutive to operations on the tuberculous depend most frequently on infection produced by the presence of common pyogenic microbes in the wounds of these subjects. In other words, according to MOLLIERE, the results of operations on the tuberculosis may be benign, provided we can avoid traumatic fever. The remote results may be good, mediocre, or bad: good, when to operative success is added therapeutical success—the cure is durable with or without mutilation; mediocre, when there is operative surgery, but the tuberculosis after variable time again appears, ending in death; bad, when there is neither operative success nor therapeutical success. In the classification proposed by M. VERNEUIL, we must take account of the circumstances which depend on the operation; the lesions of the patient and his environment. The operative results would be different, according to the general treatment followed by the patient during and after operation, and will depend upon whether a cutting instrument, cautery, or injections be used; complete or incomplete extirpations have also their effect. The results, according to BOECKEL, VERNEUIL, and OLLIER, are better in acquired than hereditary tuberculosis. M. JULES BOECKEL (Strasburg) states that out of 204 cases of amputations and resections performed for local tuberculosis, the mortality of the amputations has been double that of the resections. The results differ again, according to the seat and extent of the lesions. The region invaded is of no great importance.

The gravity of the operation, too, is different, according as the tuberculosis has its seat in the pleura, peritoneum, or finger, in the hand or foot, in the ganglions or the bones, according to one or many centres, as it is localised or generalised. We may attack with chances of success the gravest forms of tuberculosis, the lungs, peritoneum, etc. Resections of the neck give excellent results, because the patients are not obliged to remain in hospital. Two or three days after operation—thanks to antisepsis and immobilisation—they may be sent out to the pure air. The results are inferior in the case of the foot, because the patients are obliged to remain in bed for many months. They live in a bacillary atmosphere, and if not already infected, they become so, according to OLLIER, by absorbing the bacilli in the air they respire and by the food they take. In tuberculosis of the ganglions generalisation may be rapid after extirpation by exciting the neighbouring ones (DEMOSTHENE), which often appear healthy because they are small, but microscopical examination often proves that they contain bacillary nuclei (ISCOÆSCO). Ablation of the ganglions is then a bad operation, which should be interstitial injections of anti-bacillary solutions (VERNEUIL, DEMOSTHENE). In articular tuberculosis resection only allows complete ablation of the lesions. The immediate results are yet more favourable than in extirpation of the ganglia. But amputation is preferable to resection; operations on the bones give better results still; but for abscess, general tuberculosis developes with extraordinary rapidity. In certain osteo-arthrites, the bones are diseased through the whole extent of the marrow. There are tubercular nuclei, without appreciable symptom on the side of the periosteum, or of the soft parts. Previous trephining of the bone will establish the diagnosis. Partial amputations leave interminable fistulæ, and when these lesions are in certain situations, as the knee, disarticulation of the hip is preferable (LE DENTU). In osseous tuberculosis we must distinguish two forms—the one circumscribe; the other invading. The first may be cured by local action; the second yields to amputation of the member, when the means employed to arrest its march have failed (BOSQUET). In tuberculosis of the foot, the region in which conservative surgery gives the worst result—so far as the remote result—amputations and resections gave almost the same mortality; but general rules cannot be laid down, on account of the diversity of the patients, their age, social conditions, environment, etc. In infancy, intra-articular cauterisation gives the best results. In the adult, thirty to forty years of age, resection is indicated; but when the lesions are extensive, and we cannot remove all by resection, OLLIER counsels amputation. LEONTE lays down that in tuberculosis of the limbs, radical operations are preferable to sparing ones. In tuberculosis of the bladder, when palliative treatment by intra-vesical injection and internal medicine are powerless, we must act direct upon the lesion. Practise hypogastric section, and by raclage remove the diseased part of the mucous. In four cases, Professor GUYON has obtained temporary rcovery, with relief of suffering. GUYON and LE DENTU recommend permanent drainage, and the hypergastric operation to the perineal one. At the end of a certain time the drainage-tubes can be replaced by a special apparatus (LE DENTU) adapted for hypogastric fistula. The results obtained by the operation for tuberculous vesical depend above all on the state of the kidneys and the prostate. The kidneys are always attacked before the prostate, and the operation can only be put off by palliative treatment. The pain must be alleviated by injections of cocaine and boracic acid (RAVAUX). "But," said M. GUYON, "the

surgeon now-a-days does not try to palliate for a time, but to cure, by taking away all diseased tissue." Tuberculosis of the kidney may be cured by the total extirpation of that organ; that of the prostate by curage (Le Dentu); that of the eye by total ablation (Vigue); that of the uterus by raclage and cauterisation (Bouquet); that of the ovaries and the tubes by a radical operation, when there is intense pain, pelvic peritonitis, etc. (Terrillon). Operative interference then in local tuberculosis gives excellent results, as it removes the causes of infection, and prevents other parts of the body from being infected (Molliere).

Adults require a little more radical operation than children. The statistics of children cannot be applied to adults. In the infant, we can cure—according to Molliere—almost all tuberculous affections without having recourse to the bistoury. M. Leonte goes much further, for he thinks even in adults we may obtain the cure of local tuberculosis by general treatment and interstitial injections. In subjects attacked with pulmonary phthisis, with local tuberculosis, the radical ablation of the latter may be followed by immediate reunion, as in healthy subjects, and by considerable amelioration of the pulmonary lesions (Le Dentu, Molliere, etc.) In such cases it is necessary to ensure immediate reunion, and we must drain and reduce the minimum of bed.

In conclusion, thanks to antiseptic treatment, operations on the tuberculous are indicated in every case of local lesion, and the results must not be calculated from the pre-antiseptic day, as recent results are more encouraging. We must put our patients in the best hygienic conditions—salubrious surroundings, pure air, sea, if possible; submit them to a tonic and reparative course of treatment for months, and even years; administer medicines capable of destroying the bacillus scattered in the organism; disinfecting the operative part with various antiseptics—bichloride, ether, phenic acid, etc.

Annotations.

"Forsan et hæc olim meminisse juvabit."

THE ADDRESSES AT THE OPENING OF THE SCHOOLS.

We publish in this number the full text of a few of the addresses which have been delivered at the opening of the schools, and we are warranted in saying that this year the addresses have been far above the average of former years, both in point of matter and form. These introductory lectures are well worth reading by all thoughtful students and practitioners. They open out suggestive thoughts on the scope of medicine, and they elevate it on to a higher platform. It is true that roseate pictures are drawn; that in the struggle in after life, which the student will have to undergo, the ideal will have to take the wall. But it is well to have ambitions, and even though disillusion may come, it is better to have once had higher thoughts of the dignity and the scope of medicine.

DANGERS OF ADMINISTERING GAS.

The death of Lady Milne in the operating room of a dentist was very sad, and though, fortunately, it is a rare occurrence to read of an accident of this nature, yet the possibility of death should always be taken into account. Familiarity begets contempt; but it should be remembered that we cannot produce anæsthesia with impunity, and that the separation between life and death under an anæsthetic is but a degree. The chloroformist of to-day is, we believe, much more prudent than the chloroformist of the past. This prudence is highly to be commended. It has nothing to do with nervousness, but it pays due regard to contingency, and death is a contingency of chloroform administration. This lesson will not be lost upon dentists, and will check any tendency to free administration.

THOMAS'S SPLINT.

At a meeting of the Medical Society of Virginia Dr. John Ridlon, of New York, read, by invitation, a paper "On Some Practical Points in the Treatment of Hip Disease, with Special Reference to the Use of Thomas's Splint," and we are glad to see that this great invention is so justly recognised by one of the best American orthopædic surgeons. Dr. Ridlon considered the subject from the standpoint of the general practitioner, and he described other appliances. "But," said Dr. Ridlon, "to one, however, who was satisfied to treat tubercular joint disease in any part of its course without traction, or who was so circumstanced, as the general practitioner was, that he must treat all walking patients without traction, and to one who believed that immobilization, and not traction, was chiefly indicated in the management of the cases, Thomas's splint would prove of great service, as it could be made by a blacksmith and a harness-maker at a cost of not more than $2.50."

THE BIRMINGHAM SCHOOL OF MEDICINE AND DURHAM UNIVERSITY.

At the dinner of the Northumberland and Durham Medical Society, Newcastle-on-Tyne, October 5th, Mr. Lawson Tait made a very important announcement—probably intended as a feeler—that the Birmingham Medical School desired to be affiliated to Durham University. The occasion was most appropriate, as there was a thoroughly representative gathering of men interested in the success of Durham, and the proposal should receive almost unanimous acquiescence. Durham will strengthen its position, just as the Victoria University has done by its union with Leeds and Liverpool, by associating itself with such an excellent school as the Birmingham one. The question rises far above the loss of a few pupils at Newcastle-on-Tyne. Had such a spirit guided the governors of the Victoria University, then Leeds and Liverpool would have been excluded. The Birmingham scheme commends itself to us, and we trust that the proposal will be accepted, and that we shall be saved from the institution of another university.

MEDICAL ACTIONS.

We have lately had a plentiful crop of medical actions, thus emphasizing the necessity of supporting the Medical Defence Association. Dr. Eadie, of West Cocker, Somersetshire, was charged by the wife of a shepherd with an act of indecency, which rested on evidence so apparently and intrinsically groundless, that he was at once acquitted; but the result must necessarily be, apart from the anxiety and worry, that Dr. Eadie will be very considerably out of pocket. The harm done by accusations of this kind cannot be measured—for Mrs. Grundy is about—and any tale of this kind will lose nothing in the telling. Another action at present pending is against Dr. Campbell Black (Glasgow). *Pendente lite*, we cannot offer an opinion on the case, but the evidence, so far as given in the *Medical Press and Circular*, entitles Dr. Campbell Black to our full sympathy, and we do not doubt that a Scotch jury will do him full justice. But Dr. Campbell Black should not stand alone in this fight. We trust he will have the support of his professional brethren.

SENTIMENTALISM *VERSUS* SYPHILIS.

It would be only just that men who give or propagate syphilis should be punished. But we fear that such a course is impracticable. Syphilis is spread in our large cities, and we cannot ignore the existence of the agents by whom it is diffused. Some measures should be adopted to control the social evil. Compulsory registration, as adopted on the Continent, does not meet with favour from the scientific men who have studied the subject. But it appears to us that the French system has failed, owing to the penal clauses which sent the unfortunates to prison and not to a hospital. In Italy we believe that the Contagious Diseases Acts are no longer to be enforced, so that the arguments drawn from foreign customs no longer apply. Some control is absolutely demanded. Unlicensed prostitution in London, for instance, is worse than ever, in spite of police efforts, that the streets may be kept clear. But this does not diminish the evil; you do not get rid of dirt by simply putting it out of sight.

THE REGISTRATION OF MIDWIVES.

The dangers to which lying-in women are exposed from the ignorance and unskilfulness of untrained midwives are but too well known. They are worse even than revealed to us by inquests, for a good deal of the malpractice never comes to light. We are strongly in favour of the system of registration, even though it has one great drawback—that it will allow of untrained women being put on the register. This argument was applied when the Dentists' Act was framed, but it is not worth consideration. At first, no doubt, the untrained would gain, but this class would soon become extinct, as it could not be recruited. Again, it might be minimised if a clause were inserted in the registration scheme that the midwife claiming registration should have been practising her art for three years previously, and that three or six medical men should certify as to her competency. The tendency of registration should be to elevate the standard and status.

THE CONTAGIOUS DISEASES ACT AT SINGAPORE.

We have received a copy of the *Singapore Free Press*, September, 1889—an excellent English paper published in this English colony—containing a discussion at the Municipal Commission, and also a statement, drawn up by all the resident medical men, on the Contagious Diseases Act. Mr. Jiak Kim proposed a resolution to the following effect:

"That as the absence of any regulations for checking the spread of certain contagious diseases, arising from the dangerous trade or practice of prostitution, is proving injurious to the health of the public of this place, it is hereby resolved that it is expedient that steps be taken by the Municipal Commissioners to make and enforce under section 56 of the Municipal Ordinance, such regulations as may be found necessary for the protection of public health."

He supported the resolution by a quotation from Parkes:

"A great outcry has been raised against this proposal, which is yet a matter of precaution which the State is surely bound to take. A woman chooses to follow a dangerous trade—as dangerous as if she stood at the corner of a street exploding gunpowder. By practising this trade she ought at once to bring herself under the law, and the State must take what precautions it can to prevent her doing mischief. The State cannot prevent prostitution. We shall see no return to the stern old Scandinavian law which punished the prostitute with stripes and death; but it is no more interference with the liberty of the subject to prevent a woman from propagating syphilis, than it would be to prevent her propagating small-pox."

It would appear from his statement that syphilis was on the increase in the island, and that the conditions under which prostitution was carried on were different from what they are in England.

"The character and habits of our unfortunate women here are widely different from that possessed by the same class of women in England, where the females are as free and independent as the males. But the majority of our unhappy women here are not the independent persons that some suppose them to be. They are not, in the strict sense of the term, free agents, especially those young girls who form the bulk of our prostitutes. They have been in most cases sold, trained, and brought up for the sole purpose of earning money for their mistresses, whom they were taught from childhood to call mother—a word, sir, most convenient for their object in view, because it means not only blind obedience to all their commands, but it is also a word most prudent to use when they are before the eyes of the law."

Singapore comes under the English law, and it would appear from the statements of Major McCallum and Colonel Dunlop that the Municipal Commission had not the power under the ordinance to draw up any by-laws on the subject. Major McCallum put the matter very strongly in his speech:

Major McCallum said the motion as brought before the Commission was to his mind perfectly simple, and he regarded it as a point upon which that Board might congratulate themselves that it had been brought forward by one of the Chinese colleagues. Chinese prostitutes form a great portion of that unhappy class in this town, and the mere fact that a gentleman of Mr. Jiak Kim's knowledge of the wants of the place should bring forward a matter of paramount importance to his countrymen and women added weight to the address he had

delivered. In his address he had shown clearly the difference in the circumstances of the C.D.O. in England and in the Straits Settlements. There might or might not be room for argument in England, but he believed there could be but one opinion about the evil effects of the repeal of the Ordinance in this Colony. In a state such as ours things were very different, and the repeal of the C.D.O. was the most cruel and inhuman step ever taken out here. We were at present suffering from the effect of the action of a small band of sentimentalists who had used the present system of Parliamentary government to force on us that course, the evil effect of which was brought to our very doors. Nothing could be stronger than the medical evidence which they had before them; and he was informed that it was not only the opinion of the civil medical officers, but was also endorsed fully and conscientiously by those connected with the Government Hospitals. The last lines of the petition were, in his opinion, the most important of all; they said some remedy must be found by those responsible for the health of the community. He thought that part should be printed in large type. If they went on to examine what the effect of the repeal had been, he had been told that, not only here, but in the other Settlements, the number of admissions into pauper hospitals of sufferers from the foul disease would be *just double*, and large numbers more would go if there were room. Going to the troops, 15 per cent. were suffering; that meant that the Government were paying large sums of money as military contributions for a number of men who were simply a loss, in consequence of legislation forced upon us by the wish of the House of Commons. The motion had his entire sympathy in every way, and he congratulated Mr. Jiak Kim for the way it had been brought forward. But when he came to the resolution, he was met with a difficulty.

He had looked at the Act carefully—at section 56 which concerned the expenditure of money—and at 86 which made provision for bye-laws. In the former it was laid down that the Commissioners might vote money for "all matters necessary for or conducive to the public safety, health, or convenience." It might be felt that he was entirely wrong, and that the proposer and seconder read "public health" as in connection with that particular subject. Only a few days ago they had thought "convenience" had a very clear meaning, but upon it being brought to the test of a full court of appeal their case would not stand. It was therefore a little difficult to say—he fancied it was rather straining the sense to use the Municipal Funds for this purpose. Then coming to the clause about bye-laws—in spite of the extract from Parke's Hygiene and the petition they had heard read—it was straining the words of the Ordinance to class prostitution as a dangerous trade. If they passed the resolution in its entirety, they would have to do two things, vote money which would have to be approved by the Governor in Council. He was almost afraid he could see no hope that such a sum of money, under the instructions His Excellency had received, would be devoted to such a useful and beneficial end. Then the bye-law must be brought before the Governor in Council, and he might say that the opinion on the Executive Council concerning the effect of the repeal was divided, and that with such a division, and the instructions of the Secretary of State, he could see no hope of carrying it as a bye-law under the Ordinance. If the resolution had been formed in such a way that the Municipal Commissioners should take upon themselves the task of enquiring, collecting statistics, and making a report pointing out the urgent necessity of having something done with a view of a new clause in the amending Ordinance, he would immediately have voted for it. He was afraid under the conditions it was brought forward, much as he regretted it, he felt no beneficial purpose would result from the resolution, and no good could be got out of it. He would therefore have to record his vote against it.

The President (Colonel Dunlop) was perfectly satisfied that they had no power under the Ordinance to draw up bye-laws on that subject. He sympathised entirely with the object of the motion, and was convinced that the gravest injury was being done to the people of the place. At the same time he did not think that by any side wind would it ever be possible to restore the condition of affairs as they were prior to the repeal of the Contagious Diseases Acts.

THE CONTINENTAL ANGLO-AMERICAN MEDICAL SOCIETY.

The first meeting of this newly-formed Society was held at Paris, on September 30th, under the presidency of Sir Spencer Wells, one of the honorary presidents. Among those present were: The Hon. Alan Herbert, M.D., Dr. Faive-Miller, Dr. Thomas Suin, and Dr. E. Warren-Bey, all of Paris; Dr. Sandwich (Cairo); Dr. Stanley M. Rendall (Aix-le-Baines); Dr. St. Clair Thomson (Florence). A dinner was given in the evening at the Grand Hotel. The invited guests were: Dr. Worms, of the French Academy of Medicine; Dr. Schuteliz, of Homburg; Dr. Macey, London; Dr. Dean, Dr. Sœwenberg, and Dr. Landolt, Paris, with Dr. Norris, of New York, and Dr. Rogers, of Illinois. After the usual toasts had been duly honoured, "Success to the New Society" was given, to which the Hon. Alan Herbert, M.D., responded. The health of Sir Spencer Wells was proposed by Dr. Faive-Miller, and Dr. Dufrey gave the invited guests.

THE FRENCH CONGRESSES.

The great exhibition is now closed, but it has left not only pleasant memories, but useful records behind it, and not the least of which are to be reckoned the transactions of the numerous congresses in connection with medicine which have been held. The French have a talent for organisation, and the hospitality extended to foreign guests has been both generous and thoughtful. The Congress on therapeutics was most successful; whilst the records of the one on medico-legal matters is also worthy of mention. There is much divergence of opinion as to the value of these meetings, but there can be only one opinion on the necessity of encouraging the *entente cordiale* between scientific workers in different countries. Personal contact with workers in the same field is magnetic in its action. Science knows no country. These gatherings all meet on a common platform.

HELOAN.

Heloan is the name of an Egyptian thermal station which has been developed by his Highness the Khedive, and it would appear from the *Bosphore Egyptien* that it is a little Paradise, but Paradise was not perfect, and Heloan also suffers. What makes Heloan imperfect? There is no doctor. Some might be inclined satirically to remark that Heloan ought to be congratulated on this, but the Heloanise evidently do not think so. The *Bosphore Egyptien* tells a few cases where the presence of a medical man would have saved a few lives. Another grievance is that though there is an excellent pharmacy, with a resident pharmacien—a state official—no medicines can be obtained. This requires explanation. There is a medical man appointed by the administration, but this official does not live at Heloan all the year, and the pharmacien does not dispense any medicine unless it is advised by the official physician. These statements appear almost incredible, perhaps there may be some explanation for them.

A NEW CURE FOR INSOMNIA.

THE *St. Louis Globe Democrat* says, "The abuse of the eye is the crime of the age. I am prepared to demonstrate that at least nine-tenths of the prevailing sleeplessness of which we hear so much is due to nervousness directly traceable to the optic nerve. We are wearing our eyes out over books, and desks, and types, and the effect shows itself, not only in the organ itself, but in its retrospective effects on nerve and brain. Take a soft cloth—say a piece of napped towel—and fold in it two small pieces of ice at a distance apart to exactly cover the eyes when the cloth is laid across them. Then lie down, adjust the cloth with the ice over the closed eyes, and you will be asleep in a very short while.

STRYCHNINE IN THE TREATMENT OF DIPSOMANIA.

A RUSSIAN physician has, for some time, been using strychnine as a preventive of the drink crave, and he reports most favourably upon its use. This is such a very simple remedy that it should be soon placed out of dispute whether it has any value. There are but too many patients upon whom to test the poison, and we believe there is no reason to fear that strychnine will be abused as much as morphia and chloral have been, or that we shall have in place of dipsomania strychnomania.

ST. MUNGO'S.

GLASGOW has been very much disturbed over the elections at St. Mungo's. We allude, of course, to the medical section of the city. It is the old story of the Outs and the Ins, the latter being perfectly satisfied with the mode of election and with its results. The Outs on the other hand are indignant, and as Glasgow has been noted for the purity of its medical elections, and as the Outs were never guilty of buying professorships or selling them, they are all the more shocked, and some of the medical journalists have been expressing their woes in ink. Our verdict would be so far as the claims to purity of election are concerned, *arcades ambo.*

A STRANGE CASE.

The Hammersmith Advertiser contains the account of an inquest held upon the body of a woman who died from taking prussic acid, at the house of a chemist with whom at one time she had cohabited, and the poison seems to have been taken in a frenzy of jealousy. She lived for forty minutes after having taken the poison, and the chemist made no attempt to treat her himself or to send for medical aid until shortly before death occurred. When asked by Dr. Alderson, who had been sent for, why he had not sent earlier, the chemist replied, "*You forget I am partly a medical man.*" This was followed by the natural remark—"What have you done for her? Your medical knowledge must have told you that promptness was important. Forty mimutes is a long interval." People are too apt to run to chemists for medicine and to prescribe for them; they should remember that the chemist is a mere dispenser and vendor of drugs, and has neither the knowledge nor the right to prescribe them in addition. The chemist showed how little of a medical man he was, or how little he knew about things, when he could let a woman linger on for forty minutes after having taken a dose of prussic acid without attempting any treatment. Notwithstanding the fatal nature of the drug there would have been a great chance, the woman surviving for over half an hour, that with prompt treatment she might have recovered. The Coroner's jury returned a verdict of "death by misadventure."

SCALES OF FEES.

We publish in our correspondence columns the scale of fees suggested by Dr. Rentoul. It must be remembered that they are merely suggestive, and that criticism is invited. Operations in private practice are rare, because the patients can so readily enter the local infirmaries. A system of low fees for small surgical operations might induce the working classes to have the operations done at home. This is a tentative matter.

Periscope.

I.—GLEANINGS IN MEDICINE.

By W. B. KESTEVEN, M.D.

An Interesting Case of Stone in an Infant æt. Sixteen Months. By C. E. Todd, M.D., Assistant Physician to the Adelaide Hospital (*Australasian Medical Gazette*, August, 1889).—On the afternoon of May 16th I was called to see a child æt. sixteen months. The mother told me that he had passed no water for upwards of twenty-four hours, and that he was in great agony. On examining his abdomen I found the bladder distended up to the umbilicus; its shape could be clearly seen through the bulging abdominal walls. The child was struggling and straining violently, and a few drops of urine were dribbling away every now and then. The mother took him at once to my house, and with some difficulty I passed a No. 4 silver catheter, and drew off three pints of water. Just as the catheter passed into the bladder it struck against a stone. I was unable at this time to pass a sound, because the child had a very light prepuce, and I could not get the point into the urethra. On May 18th I had everything ready to do lateral lithotomy. I slit up the tight foreskin, and enlarged the urethral orifice to allow the sound to pass. I introduced the instrument half an inch, when it struck the stone firmly wedged in the urethra. I removed it with the scoop of an ordinary director. The calculus was a uric acid one, with a slight phosphatic deposit, of an ovoid form, and the size of a large pea. This case seems to me of interest, (1) because the child had no symptom whatever until complete obstruction came on; and (2) because, looking at the stone afterwards, one would not have thought it possible that so large a body could pass along the urethra of so young a child. The stone must have passed along the canal in a very few hours, because I sounded a second time on the afternoon of May 17th, and it was then in the bladder.

Medicine in Japan.—The editor of the *Australian Medical Gazette* gives the following notice of the journal of the Sei-I-Kwai, or Society for the Advancement of Medical Science in Japan. It is published monthly, one half being printed in English, the other in Japanese; an index for both parts is printed with each number in English. It is a most interesting publication, and no number is issued in which some article is not published in English, which is of special interest to medical practitioners of all countries; some of these articles are by European or American members of the society, but the majority are by Japanese practitioners possessing European qualifications. The society is managed by a committee, of whom six are Japanese, and three European or American gentlemen, the president being Kanehiro Takaki, F.R.C.S. Eng., Director General of the Medical Department of the Japanese Navy. The reports of discussions which take place at

the meetings of the society are most interesting, and show such high professional acumen on the part of the practitioners taking part in them, as to be a worthy example to similar societies in these colonies. Of the value of the Japanese portion of the journal we, unhappily, not possessing erudition in that language, are only able to judge by the titles of the papers read, subjects discussed, or cases reported; but from this it is manifest that the Japanese practitioner is possessed of high intelligence, and has an appreciative love for his profession. We have now before us the numbers for April, May, and June of this year, and each Japanese portion contains upwards of a dozen original articles, reports of cases, and discussions on medical subjects. Amongst them, in the April issue, appears "Report of *post-mortem* of a case of Stricture of the Duodenum, by Y. Sanayoshi, F.R.C.S. England." "Treatment of Cancer by Ozone Water." "Phthisis from House Sweeping." "Intubation of the Larynx." Also an extract from the *Government Gazette*, "Regulations relating to Apothecaries and to the Preparation and Sale of Medicines."

In the May issue, we find, under "Proceedings of the Society," discussions on "Ulcer of the Leg," and on "Erysipelatous Vitiligo," with papers on "Clinical case of Aneurism with Autopsy," "Efficacy of a Lotion of Antipyrin in Suppuration of the Anterior Chamber," "Treatment of Cholera." In the same number are, under "Proceedings of Society," discussions on "Ascites," and on "Disorder of the right Knee-joint," with papers on an "Examination of Oysters as to an Endemic Disease in Miura Gori, Uanagawa Ken," "Observations on Diphtheria," "Artificial Maturation of Cataract," and on "The Therapeutic Effect of Washing out the Stomach in Diseases of Infancy."

Our readers cannot fail to see that practitioners who feel such an interest in, and possess such knowledge of professional subjects as is exhibited by the foregoing examples, must be of high intelligence, and can only form part of a nation which possesses the attributes for national greatness. This is the more astonishing when we remember that thirty years since, with the exception of two or three ports, Japan was sealed against Europeans and their knowledge, and that all the progress which we chronicle has come about in the latter half of this period. The care which the Imperial Government of Japan takes for the protection of its people against ignorant pretenders in medicine is an admirable example to the Australian Colonies; and the present is an especially opportune time, there being, either before the Legislature or in contemplation, Bills for the regulation of the practice of medicine in four of the Colonies.

Case of Double Parotitis of a Reflex Organ (*Meditzinskïa Pribavlenïa R' Morskomü Sbozniküi*, April, 1889, p. 352, and *Journal of Laryngology*, October, 1889).—At a meeting of the St. Petersburg Naval Medical Society, Dr. Mïlonas communicated the following curious case: An exceedingly nervous and emaciated recruit, aged twenty-two, fell ill with a severe attack of right-sided croupous pneumonia. On the third day there supervened incontinence of urine, alternating with retention; while on the ninth there was developed a prostatic abscess, determining a complete prolonged retention, and necessitating catheterisation. The latter proved to be extremely difficult, since, on one hand, any attempt at introducing the instrument into the urethra gave rise to general clonic convulsions; while, on the other, the end of the catheter deviated from the urethra into the prostatic abscess. Several hours after these repeated and prolonged manipulations there suddenly appeared rigor and pain about the right temporal region, which were swiftly followed by intense swelling of the corresponding parotid, rapidly passing into suppuration. The patient's micturition being at the time restored, no catheter was used for the next six days. On the seventh, however, another prolonged attack of retention of urine took place, and the catheterisation was again resorted to. It was most rapidly followed by the development of a left-sided suppurative parotitis. The patient ultimately recovered, though but very slowly. Analysing his case, Dr. Mïlonas comes to the conclusion that on either occasion parotitis was caused in a reflex way by the said intense irritation of the patient's genito-urinary tract.—During a discussion Dr. Balinsky adduced three similar instances of reflex parotitis from his own practice, all referring to women. In one of the patients, who had undergone some operation for vesico-vaginal fistula in the morning, the subsequent insertion of a catheter *à demeure* was followed at night-fall by swelling of one of her parotids. In another, suffering from uterine flexion, the introduction of a sound into the womb gave rise on each occasion to a rapid painful enlargement of the gland. In the third, parotitis developed shortly after the amputation of the womb, preceded by the introduction of a catheter into the bladder.

A Photographic Study of the Laryngeal Image during the Formation of the Registers of the Singing Voice (*Journal of Laryngology*, October, 1889).—This paper is an attempt on the part of Dr. French, whose industry as a laryngeal photographist, is so well known, to clear up the vexed question of the vocal registers. The conclusions that he draws from hundreds of photographs of the larynx in the act of uttering certain notes are as follows:

1. That protrusion of the tongue does not alter the laryngoscopic appearances.

2. That in the female there are three registers. This renders two changes necessary in the mechanism of the vocal cords, which changes are always accompanied by changes in the quality of the voice. The lower break occurs at or near F sharp, treble clef, first space; and the upper break an octave higher than this note. The change of mechanism consists of a shortening of the vocal bands, an appearance of an increase in their tension, and a change in the shape of the chink of the glottis, and it is usually accompanied by a backward movement of the epiglottis. The change in the shape of the chink at the lower break consists usually of a wider opening of the ligamentous portion of the glottis, and partial or complete closure of the cartilaginous portion. At the upper break the chink may simply be reduced in length and width, or a part of the ligamentous and all of the cartilaginous portion of the glottis may be closed.

3. That in male voices possessing the falsetto range there are two registers; the change from the chest to the falsetto usually occurs somewhere between C sharp bass clef, first line above stave, and the F sharp above. The change in the mechanism consists usually of a sudden shortening of the vocal bands—though occasionally they are increased in length—an appearance of increased tension, and an alteration in the shape of the glottic chink. The edges of the vocal bands may be brought into opposition in front or behind, or both in front and behind, or the chink of the glottis may be open in its entire length, in which case the shape is altered, but the area of the space between the vocal bands is about the same as is necessary for the production of the note before the break. The falsetto notes are therefore produced by stop closure and change in the length and tension of the vocal bands, or by change in their length and tension without stop closure.

On Excision of Enlarged Tonsils. By L. S. Zisman, Irkütsk (Proceedings of the Irkütsk (East Siberian) Medical Society, 1889, p. 10, in *Journal of Laryngology*, October, 1889).—The author describes twenty-two cases of hypertrophied tonsils, observed by him during the last three years, and treated by excision, four of them referring to adults, the remainder to children aged from three to nine. In all the operation was made painless by previously painting the fauces with a 4 per cent. solution of cocaine. It lasted usually a few seconds, never longer than half a minute. For a few days after, the patients were made to frequently gargle their throats with a solution of chlorate of potash. In one of the cases a rather alarming hæmorrhage from the wound occurred several hours after the operation, which, however, was ultimately arrested by ordinary means. In the other cases, parenchymatous bleeding was invariably trifling. The after-course was apyretic, except in one case where, on the next day, slight fever occurred, which probably depended upon the use of an unclean instrument. Children are said to bear the operation "beautifully." The best instrument is thought to be Luer's tonsil guillotine, its advantages being: (1) It permits the operator to act with one hand, while the other is occupied with depressing the tongue by means of a rectangular spatula; (2) Its fork drags the gland into the ring before the excision (and not during the latter, as in other instruments of similar kind), which enables the operator to remove the gland most thoroughly; (3) The instrument can be easily taken to pieces, which allows it to be kept in the most cleanly condition.

Full and Final Failure of Pasteur's Rabbit-killing Virus.—The following appeared in the *Standard*, of September 2nd, 1889:—"After more than two years of investigation, the International Rabbit Commissioners have issued their report. About 1,400 schemes for the destruction of rabbits were brought out by the offer of £25,000 by the Government of New South Wales; but not one has been deemed satisfactory. The chief interest centred in M. Pasteur's plan of spreading chicken cholera among the rabbits, and great hopes were entertained of this method. After many test experiments, however, it was ascertained that while the virus of the disease when given to rabbits in food proves fatal, the affected animals do not infect others. Under these circumstances, the Commissioners prudently decline to recommend the dissemination through Australasia of a disease unknown in the Colonies, but which is disastrously epidemic among fowls in some countries. The report discusses the evidence as to other similar plans, and concludes that there is no known disease communicable to rabbits which would, by dissemination, prove extensively destructive to them, without risk to other animals. The Commissioners fall back on the old remedy of erecting rabbit-proof fences, the wire netting to be at least three feet high, with five-eighth inch meshes. This they would make compulsory, together with the

destruction of rabbits by occupiers of land, and by the State on land not occupied. A Bill has already been introduced to carry out the recommendations of the Commissioners in Victoria."

Classification of Disorders of Speech. By Dr. Chervin (*Le Progrès Médical*, September 28th.)—Dr. Chervin, at the International Congress of Otology and Laryngology, held in Paris, submitted a table giving a classification of the disorders of speech. Speech, Dr. Chervin observes, depends (1) on the formation of ideas and words; (2) on the coördination of ideas and their transmission; (3) the articulation of words by the phonetic organs. A corresponding group of disorder attends each of these physiological terms: 1. Disorder of thought may be permanent, due to mental disease, or transient, as in anger, etc. 2. Disturbance of coördination, and of the transmission of ideas, are divisible into those with or without organic lesions; in the first group he placed agraphia and aphemia; in the second, stammering and spluttering. 3. Disorders of articulation were arranged according as the defects were seated in the palate; due to hare-lip, or to disorders independent of organic defects—*e.g.*, lisping, etc.

Exalgine. By Dr. Hepp, of Mulhouse (*Le Progrès Médical*, 28th September). MM. Dujardin-Beaumetz and Bardet have recently called attention to the analgesic properties of this substance, as demonstrated by M. Brigonnet, in order to indicate its special action. It was discovered in 1874 by M. Hofman, and termed by him *Méthylacetanitide*. Dr. Hepp has noted its effects during two years, and regards it as a febrifuge or antifebrine in doses of 0.25, beyond which dose it produces vertigo, with loss of consciousness. These symptoms, however, are reported to have rapidly passed away. Exalgine is also reported to be of service in neuralgic affections.

On the Diagnosis and Treatment of Obstructions of the Eustachian Tube. By Dr. Saurez de Mendoza (International Congress, Paris, 22nd September, *Le Progrès Médical*).—The author recognises:—1. Catarrhal obstructions, permanent and transient. 2. Organic obstructions or permanent contractions. These latter are much more common, Dr. Mendoza observes, than is generally supposed. For the purposes of diagnosis the author uses whalebone bougies, graduated for the purpose of indicating the seat of the narrowing of the passage. The bougie is marked in tenths of a millimetre. Dilatation is practised intermittently or continuously, and may be completed in from eight to seventeen or more sittings, varying with the extent of the contraction.

The Use of Menthol in the Upper Air-Passages. By Dr. F. H. Potter, Buffalo, N.Y. (*Journal of Laryngology*, October, 1889).—The drug controls superficial inflammation; that it is an analgesic, and second application can be made in increasing strength without discomfort; that it is destructive of some of the low forms of life, especially the bacillus tuberculosis, and that it is a valuable antiseptic in nasal surgery. It has an important place in the treatment of atrophic conditions. It can be used in strength of from one to fifty per cent., dissolved in oil. The oleum petrolia the author considers the best for the purpose of dissolving the drug. It can be applied directly by cotton application, or by means of the spray, or by vaporisation. The direct method answers best in the pharynx, the spray and vapour for the nose and larynx. Five cases of laryngeal phthisis following upon disease of the lungs were also reported, in which the menthol treatment gave satisfactory results, the local conditions improving rapidly under its use.

Menthol in Laryngeal Phthisis (*ibid*). By Dr. Chas. H. Knight, of New York.—Twenty cases, most of them of a severe type, treated with menthol applications, furnished the author ground for believing that this is a valuable agent in tubercular laryngitis. The drug was dissolved in fluid cosmolene in the proportion of a drachm or a drachm and a half to the ounce, and applied by means of a laryngeal syringe, or in the form of spray, by a nebuliser or vaporiser. In nearly all cases the subjective symptoms and the local appearance improved. In no case did complete healing of an ulcer take place. In this respect the author's experience does not bear out the representations of Rosenberg and others. Three propositions are offered: (1) spontaneous cure of a tubercular ulcer of the larynx may occur; (2) a simple erosion or ulceration may be mistaken for a tubercular ulcer; (3) the best results from local treatment of the larynx may be expected in cases of incipient or limited pulmonary disease, and in primary laryngeal tuberculosis.

The Nature of Ozæna, and some Remarks on Epithelial Metaplasia. By Schuchardt, Stettin (*Volkmann's Sammlung Klinischer Vorträge*, No. 340, in *Journal of Laryngology*, October, 1889).—The author is not satisfied with the conceptions of the nature of ozæna at present put forward by different authors. He originates a new theory of the cause of the fœtid odour of this disorder, and it must be said that his views are very convincing. He says that it is always the case that if cylinder epithelium is changed into plastic epithelium the secretion of a mucous membrane becomes fœtid. Thus old otorrhœas and catarrhs of the uterus give a fœtid secretion. He has found microscopically that the nasal mucous membrane of patients with ozæna is rich in plastic epithelium, and he also finds it in the secretion. It is possible that the fœtid nature of some cancroids of the mucous membranes and bronchitis putrida can be explained in the same manner.

A New (?) Treatment of Measles and Whooping Cough. By Dr. Cohen (*Journal de Médicine de Paris*, September 29th.)—Dr. Cohen observes that the danger in measles and whooping cough lies in the complications which attend these diseases—*e.g.*, bronchitis and pneumonia, and which may be coincident with the appearance of the eruption on the skin and on the mucous surface of the bronchi and pulmonary vesicles. The broncho-pneumonia secondary upon measles or whooping cough will occur either from want of judicious treatment, or from the carelessness of the patient. The novelty of treatment proposed by Dr. Cohen consists in keeping the patient in a warm room, and administering repeated full doses of acetate of ammonia. This medium, Dr. Cohen urges, is eliminated by the lungs and destroys the microbes. The same journal contains the account of a plan of treatment of whooping cough (by Dr. Leblond), consisting in the vaporisation of resorcin, by the heat of a spirit-lamp, every two hours, night and day.

II.—SELECTIONS FROM CONTINENTAL MEDICAL JOURNALS.

By G. F. Cadogan-Masterman, M.D.

Diabetic Coma. Dr. Gaston Lyon (*Revista de Ciencias Médicas*, Barcelona).—During the last few years the subject of diabetic coma has been very laboriously investigated, especially in Germany, and its pathology determined with highly probable exactness by the researches of Kussmaul. Nevertheless, the primary source of the insensibility is still an object of theory and research. The doctrine of acetonæmia, which has been so generally accepted, is not founded, it seems, on irrefragable data; the perchloride of iron test, so often relied upon as proof of its existence, and the apple-odour of the breath being neither exact nor conclusive; for the former, although it is a pretty clear indication that acetone *has been* present, is really no test at all of its existence when that reagent is used. Iron is chemically so eputhematous, is reddened in so many reactions, that all cases reported as acetonæmia on the evidence of this most common of tests alone are quite untrustworthy. And the latter may be often perceived when the presence of acetone cannot be proved, and when, in fact, we have tolerably clear evidence that it is not there at all.

Coma is most frequently seen amongst the younger victims to diabetes; Buhl gives one case at sixteen years, and Dreschfeld found 70 per cent. between the ages of twenty and forty years. And its fatality is very high: Frerichs reports that amongst 250 cases coma was the cause of death in 153. According to some authorities, this termination of the disease may be of our making. Pavy says that severe diabetes, if left to itself, terminates in tuberculosis; if treated, in acetonæmia. The checking of the excretion of sugar is not always evidence of its lessened formation; and Cohn has shown that this is itself toxicant if given in excessive quantities. He injected into the stomachs of several rabbits doses of forty grammes of sugar, with the result of inducing fatal convulsions in them all. And the use of opium in reducing the quantity carried off by the urine adds, at the same time, to the danger of the early supervention of death by coma.

The theories of the pathology of this condition may be arranged in two groups. In the first, that it is due to some structural alteration in the nervous system, in the kidneys, or the heart. And in the second, to the production of a poison by the anomalous fermentation of the glucose in the blood. The first theory has the initial difficulty that in the *post-mortem* room we do not find any lesion which can be definitely referred to the disease. There may be anæmia, œdema, or (*pace* Wilks and Moxon) congestion of the brain, sometimes sclerosis. Again, there may be found cerebral hæmorrhage, or softening, meningitis, or embolism. These may have caused the coma, but what caused them? Abeles has found in three cases, he says, an accumulation of glucose; but he does not seem to have determined if it existed in the serum there in greater quantity than in that of the body generally; if it did, it may have been—viewed in connection with the experiments of Cohn—really the *origo mali*.

In the kidneys, lesions more or less grave are frequently found: Griesinger detected thirty-two examples in sixty-four cases; whilst Dickinson found only two sound amongst twenty-seven; and Taylor, in two cases he examined, demonstrated marked fatty degeneration of the epithelium. It is doubtful, however, if we can fairly class these as the result of diabetic mischief; for not only may Bright's disease co-exist with it, but the profound cachexia induced by the diabetic

condition obviously predisposes to the development of the former. Therefore, whether we find necrosis of the cells of the looped tubes, or those of the medullary rays—which German pathologists called the lesion of Ebstein—or the hyaline degeneration of Armanni, it is clear that we have conditions which are not characteristic of diabetes, but of renal disease, which most commonly exist without the presence of glycosuria, and which have no necessary connection with it.

We must not reject, however, the evidence afforded by the experiments of Alberteni and Pisenti, who have produced albuminuria and alterations in the renal epithelium of dogs and rabbits, from the granular state to necrosis, by repeated doses of acetone, and which they have called "acetonic nephritis;" although, as we shall presently see, this agent has, in spite of its evil reputation, been given to human beings in large and continued doses without any apparent mischief whatever.

Griesinger, Burch, and Wunderlich have sought to assimilate diabetic coma with uræmia, since they observed such symptoms as anuria, vomiting, and diarrhœa preceding the coma in diabetics who were passing albumen as well as sugar, and when the autopsy disclosed the usual lesions of Bright's disease. But, besides the fact that the two maladies may exist together, it is quite possible to distinguish between the encephalopathia uræmica and diabetic toxæmia. Uræmia is accompanied with convulsions, which, except perhaps in the case of children, never accompany diabetic coma in human subjects; and there is a peculiar odour of the breath and urine characteristic of glycosuria, and never present in true uræmia. Eliminating the mixed cases, it is impossible to refer all the rest to the presence of urea from renal insufficiency; especially when oliguria is not the common accompaniment of diabetic coma, although we might expect that it would be so, for the irritation of the kidneys by the passing of the sugar and the degeneration of the tube cells due to it provide the very conditions which predispose to acute desquamative nephritis.

In the stomach and intestines there are alterations which Buhl compares to those of cholera; probably a kind of chronic dehydration of their walls. Fatty degeneration of the heart has been observed in several cases, and this may lead to a death by syncope, hardly to be distinguished, except by its suddenness, from coma.

Balthazar Foster states that the red cells of the blood are deformed, shrivelled, and dentated, in diabetic coma. Frerichs has never been able to find this during life. Probably both statements are correct; a drop of blood containing much sugar, and, therefore, with its specific gravity greatly raised, would by exosmosis very quickly shrivel the cells under the microscope, but they may be able to resist this deformation whilst alive. An excess of fat cells has been often found, with lipomatous deposits in the capillaries, especially in those of the lungs, and, it is said, have even been detected by the ophthalmoscope in the fundus of the eye.

The dehydration of the tissues both by the polyuria and the hygroscopic action of sugar—which absorbs water as salt does, although, as it is not deliquescent, not so greedily—is strongly insisted upon by Hilton-Fagge, Taylor, and Bouchard; and they suggest that this sugar-pickling of the brain may be the direct cause of the coma; and the experiments of Bohn again recur in connection with it.

If this be really the case, the most rational treatment would seem to be the lowering of the specific gravity of the blood by intervenous injections of water or very weak saline solutions. The author mentions this, however, only to deprecate it, since the dehydration of the tissues may simply be a *post-mortem* change, and not the cause of death.

The second theory supposes that the coma is due to auto-intoxication, and the agent generally believed to cause it is acetone. In its pure state this is a colourless liquid, with an odour recalling that of apples mixed with chloroform, is soluble in water and alcohol, boils at 56° C., and burns with a white flame. The tests for its presence are, first, the odour of the breath, which is misleading, then that of Lieben, which requires the urine to be distilled, and the distillate to be treated with iodine and carbonate of potash, to produce iodoform—which is fallacious—for alcohol gives precisely the same reaction.

The best is that of Legal: Add to the urine, diluted if it contain much sugar, a few drops of a solution of nitro-prusside of sodium, then caustic soda until it is strongly alkaline. A purple colour is developed, if acetone be present, which soon passes into yellow; then cautiously add with a pipette a few drops of strong acetic acid, so that the latter shall float above the alkaline solution; at the line of contact the liquid becomes carmine in tint, deep in proportion to the quantity of acetone present. The old perchloride of iron test is quite illusive. Pure acetone does not redden it, but it assumes this tint in the presence of diacetic acid, which is a derivative of acetone, and, therefore, as has been already mentioned, shows that it may have been present.

Brand was the first who noticed the apple odour of the breath. Peters, in 1857, confirmed it, and discovered acetone in the blood and urine. In 1860 Kaullich's paper was published, in which the production of this body was referred to the fermentation of sugar under the influence of a micro-germ—the *sarcina ventriculi*—with the by-products of alcohol, acetic acid and water. He mentioned, also, that he had found acetone in the urine of patients suffering from scarlatina and measles.

Kussmaul injected acetone in doses of from eight to ten grammes beneath the skin of animals, and obtained an artificial diabetic coma with the laboured respiration which is one of its characteristics. But he found, at the same time, that its administration to his hospital patients in repeated doses of from four to six grammes seemed to occasion them no inconvenience whatever. He explained this discrepancy by the theory that the human system, at first unaffected, became gradually intolerant of the drug, most evidently so in men of debilitated constitution.

In spite of this difficulty, the opinions of Kussmaul were almost universally accepted, and may be thus formulated: (1) An odour resembling acetone can be constantly detected in the breath and urine in cases of diabetic coma. (2) That it is produced in the stomach by a combined alcoholic and acetic fermentation. (3) That the symptoms of the above state can be simulated by the injection of acetone into the blood. In 1883, however, doubts were thrown upon the accuracy of these statements by Frerichs, who made an extensive series of experiments upon men and animals to test their reliability. He found that acetone could be freely administered to the former in large doses, with no particular result beyond drowsiness, and that although animals were injuriously affected by it, in no instance were symptoms identical with diabetic coma produced. He found, too, that it could be detected in the urine of nearly all patients suffering from acute pyrexia.

Jaksch, in a series of important papers,[1] showed that acetone is a physiological product from the decomposition of albuminous substances belonging to the body itself, that it is a constant accompaniment of pyrexia, some forms of carcinoma, of hepatic cirrhosis, and pyæmia. In diabetes it is always present, in small quantities in the slighter cases, and larger in the more severe. It is in these latter that the urine is reddened by perchloride of iron, and which he showed was due to the presence of diacetic acid, and not to the acetone it accompanies. He found it in the urine of 130 patients suffering from various forms of fever. But he introduced an unfortunate source of error by relying upon Lieben's test, which gives the same reaction with alcohol, and which greatly detracts, therefore, from the value of his laborious observations. This was avoided by Penzold (*Arch. of Klin. Med.*, 1884), who used nitro-benzaldehyde, which, in the presence of acetone, gives a deposit of indigo blue. He found that although commonly produced during pyrexia, it was not universally so, and reverted to the older idea of its action in producing diabetic coma.

Dreschfeld experimented largely, both on the sick and the healthy, with the result that the acetone had little effect on either. He took twenty grammes himself, with only the inconvenience of a headache, and could find but a trace in the urine, the greater part being eliminated by the lungs. Administered to diabetics, it simply made them sleepy, *but the urine contained it for several days afterwards.* Patients suffering from hepatic cirrhosis showed the same peculiarity. It would seem, then, that although it is eliminated by the lungs, it has to previously undergo some change in the liver, and this explains why the peculiar odour of the breath is not that of acetone, and why any profound disease of the liver delays its escape, and therefore increases its physiological effects. If produced in the system by the metabolism of albuminous tissues, and with a deranged liver hindering its escape, it may readily convert the "sleepiness" of the above cases into fatal coma; while the profound changes (eminently abnormal) which lead to its formation must be another factor of danger, increasing *pari passu* with its own production. As there is so much doubt as to the *rôle* of acetone, it has been suggested that its colleague, diacetic acid, may be the more active. But the experimental results run in much the same groove. It seems to have little action on the healthy; but when, from some failure in eliminative function, it is retained, then analogous mischief ensues.

There remains the most recent theory—that of acid-poisoning. This was propounded in a paper by Walter in 1877 (*Arch. f. experim. Pathol. und Therap. Berlin*), but attracted very little attention at the time. He injected into the stomach of various animals now phosphoric, then hydrochloric, or salicylic acid, in doses of seven to eight decigrammes to each kilo of their weight twice a day. He noticed a remarkable and corresponding reduction in the amount of alkali in the blood, and that a small increase in the dose of acid was speedily fatal to rabbits. The dog, however, seemed little affected by it; but it was noticed that an increasing amount of combined ammonia appeared in the urine: in other words, the dog could resist the poisonous action of the acid, because he possessed the power of secreting sufficient ammonia to neutralise it, which the rabbit does not seem to be provided with.

(*To be continued.*)

III.—NOTES FROM FRENCH JOURNALS.

By H. R. Hatherly, M.R.C.S.

Ergot of Rye in the Night Sweats of Syphilis (*Journal de Medicine de Paris*).—The best drugs for the prevention of the profuse night sweats of phthisical patients are, according to Dr. Pouchard, sulphate of atropine, white agaric, and phosphate of lime. But there are cases in which the perspiration is so abundant that waste of tissue and debility ensue, and all remedies have hitherto seemed powerless. It is in these obstinate cases that ergot of rye often proves of great value. One gramme of powdered ergot should be given at bedtime, or better still, half an hour before the sweat commences, and if necessary the dose may be repeated in two hours. The treatment should be persevered in for three consecutive nights, and the perspiration will be checked after the first or second day, the good results often continuing for one or two weeks. A subcutaneous injection of ergotine may be substituted for the ergot.

Emulsion of Vaseline with Water (*Journal de Medicine de Paris*).—Water and vaseline have until quite recently been considered incompatible, but Dr. Krebs has accidentally hit upon a method by which ointments may be prepared containing vaseline and aqueous solutions. It suffices to add two drops of castor oil to each gramme of aqueous solution in order to prepare with vaseline a perfectly homogeneous ointment. The chief disadvantage of vaseline being thus removed, its use will become more general in the preparation of ointments containing iodide of potassium and other unstable salts.

Senile Epilepsy (*L'Union Médicale*).—Under this title Dr. Crocq, of Brussel, describes a variety of epilepsy to which the aged are liable, and which is often mistaken for cerebral congestion. It is caused by chronic endo-arteritis of the basilar trunk. The attacks usually commence at the age of about seventy-six, often occur frequently, and may terminate in cerebral hæmorrhage or ramollissement.

Albuminuria in Typhoid Fever (*L'Union Médicale*).—Dr. André, of Toulouse, thinks that albumen always appears in the urine of typhoid patients, especially during the earlier stages of the disease, and as this is a constant symptom it becomes an important factor in arriving at an early and correct diagnosis.

Hypnotism in Confinements.—Dr. Fanton, of Marseilles, claims to have obtained through means of suggestion absolutely painless confinements. Once when he suggested to a patient that she was not to have any pain, she misunderstood him to mean "do not have any uterine contractions," and the result of her mistake was that she continued in labour four days.

Treatment of Orchitis (*L'Union Médicale*).—Dr. Dupan, of Toulouse, applies iodised cotton-wool to the scrotum. He has treated a hundred case of orchitis more or less serious in this way, and has invariably obtained a considerable remission of pain within twelve hours, and the disease has been cured in about eight days. If the treatment is commenced early enough, a cure may be anticipated in about three days. The induration of the epididymis disappears in about a fortnight.

Danger of Laparotomy performed by Gas Light (*Gazette de Gynécologie*).—Zweifel has observed on several occasions when laparotomy has been performed by gas light, that not only the patient, but even the operators experienced a slight roughness of the throat, especially when the operation was a protracted one. Several patients who had undergone operations at the Gynæcological Clinic at Leipzig, in which this roughness was experienced, subsequently developed catarrhal pneumonia. A patient, who had completely recovered after operation, afterwards succumbed to this pulmonary inflammation. The cause is sufficiently obvious. The chloroform becomes decomposed by the light of gas or petroleum; the smell of the products of this decomposition has sometimes become so pronounced that it has been thought some material was burning in an adjoining chamber.

Bromide of Ethyl as an Anæsthetic (*La Semaine Médicale*).—When operations of little importance, and of short duration, are needed, there is a reluctance to administer chloroform, owing to the mishaps which sometimes result therefrom; and although it may be urged that these mishaps are comparatively rare, there are other drawbacks which render it unsuitable for minor surgery. According to recent experiments of Dr. P. Eschricht, of Costin, we have in bromide of ethyl (bromethyl or bromidised ether) an anæsthetic, which can be easily administered, and might in many cases be advantageously substituted for chloroform. This is no new discovery, for it has been employed by Nunneley and Richardson, but it seems to have been rather neglected of late years until again brought into notice by Asch. Bromide of ethyl is a clear liquid, without colour, and having a smell which is not at all disagreeable, so that patients inhale it without any repugnance. After a few deep inspirations the first symptoms of anæsthesia appear, the face and cheeks flush, and a slight perspiration appears, the eyelids close, and in a short time insensibility is complete. Occasionally the patient seems to retain some degree of consciousness, but nothing is remembered on awakening. The advantages of bromide of ethyl are, according to Dr. Eschricht (who has used it very frequently), as follows: There is no danger; anæsthesia is very rapidly induced; there are none of the unpleasant after-effects of chloroform. The only inconvenience is that the breath has a disagreeable smell for a day or two after its administration. It is however, evident that it is only suited for minor operations, as anæsthesia cannot be long maintained. It should be known that bromide of ethyl is readily decomposed by light, and that it should be kept in a coloured glass bottle, hermetically sealed. Care should be taken to secure a very pure drug, of a specific gravity about 1.471. Bromide of ethyl is administered in the same manner as chloroform.

Poisoning by Antipyrin (*La Semaine Medicale*).—Dr. H. Berger relates the case of a young woman, æt. twenty-two, strong and healthy, who took one gramme of antipyrin for violent headache. Shortly after swallowing the drug she suffered from a burning sensation at the level of the stomach, in the mouth and the œsophagus; also from angina and dyspnœa. The face was flushed and œdematous, the eyelids and lips swollen, and an abundant secretion of tears and saliva took place. On the following days the face continued to be slightly swollen, and pressure over the parotid and submaxillary glands was painful. It would appear to have been the result of an idiosyncrasy, as the same remedy obtained from the same source was administered to several other patients with impunity.

Treatment of Tuberculosis of the Testicle (*Annales D'Orthopèdie*).—It is the opinion of Dr. Verneuil that iodoform inhibits the development of tuberculosis, and his experience leads him to think that the removal of one testicle often gives an impetus to the disease which immediately attacks the other. He therefore reserves the extirpation of the testicles for cases in which the lesions are in an advanced stage. In less severe cases he prefers interstitial cauterisations, he searches out the nodules which he pierces with a pointed thermo-cautery. In the cavities thus produced he inserts a pencil of iodoform which is allowed to remain. He considers that this method of treatment gives satisfactory results, and rarely excites any increase of the diseased action. It also saves the testicle, or at least appears to do so, and many patients attach great importance to the preservation of their sexual organs. It is not uncommon for castration to be followed by suicidal ideas.

Iodoform in Chronic Metritis (*Journal de Medicine de Paris*).—Drs. Roux and Schnell, whilst admitting the value of curetting in certain cases of metritis, believe that a more simple treatment often yields good results. They recommend intra-uterine dressings of iodoform, and affirm that the treatment by iodoform has already given good results both in obstetric and gynæcological practice. There are two ways in which iodoform may be employed—in pencils and in injections. The pencils are prepared by incorporating the iodoform with a mixture of gum arabic, gum tragacanth, and butter of cacao, or gelatine. For butter of cacao the proportion of iodoform should be one in seven; with gelatine two parts in eight. The crayons prepared with butter of cacao are hard and brittle; those made with gelatine are soft and elastic. They are introduced into the uterine cavity by means of polypus forceps, directed by two fingers of the left hand in the vagina. The injections may be made by forming an emulsion of iodoform with oil or glycerine and solution of gum tragacanth. This emulsion can be injected through a sound by means of a Pravaz syringe. All instruments should be disinfected carefully by boiling them in water, or with a solution of corrosive sublimate.

Poisoning by Cocaine (*L'Union Médicale*).—Dr. Mattison records two fatal cases of poisoning by chlorohydrate of cocaine. A third has just been recorded by Dr. Montelli. A young lady swallowed, by mistake, five grammes of a solution of the alkaloid in water, containing a proportion of 30 per cent., equivalent to a dose of a gramme and a half. The facts observed at the *post-mortem* examination were as follows: 1. Persistence of rigor mortis of the inferior maxilla and joints for a much longer period than the extreme limit usually observed of rigidity. 2. Injection of the vessels of the encephalon and spinal cord. 3. Vesicular emphysema of the lungs. The heart had ceased to beat during its diastole, and the right ventricle was full of clot. 4. The intestines and mesentery were much congested, and all the splanchnic organs were gorged with blood.

Dangers in Medical Practice (*Lyon Mèdical*).—Two deaths of medical men have recently occurred from disease contracted in the discharge of professional duty. Dr. Cotard died from diphtheria, he having become infected whilst attending his daughter, although she happily recovered; and Mr. Victor Laboré, a medical student, contracted typhoid fever whilst attending his father, who died a few weeks before his son.

IV.—NOTES FROM RUSSIAN, POLISH, AND SWISS JOURNALS.

By Valerius Idelson, M.D., Berne.

Malarial Fever and Puerperium.—Dr. Valerius E. Krusenstern, of Tiflis, publishes an interesting paper (*The Trans-Caucasian Lying-in Hospital Reports for* 1889, p. 59) on malarial fever appearing in the course of the puerperal period, in which he argues that (1) malarial fever generally, its remittent form in particular, does not in the least retard the *post-partum* involution of the womb, the organ decreasing in its bulk, just as it does under perfectly normal conditions. True, several authors have described cases of uterine subinvolution in malarial puerperal women. The real cause in such cases, however, should be sought, not in malarial process or virus itself, but simply in an inter-current endometritis accidentally complicating the fever. (2) On the other hand, malarial fever manifests a very marked influence on the functions of the mammary glands, since the appearance of the disease in puerperal women is invariably followed by a striking decrease in the secretion of milk.

Iodine in Detached Retina.—At a recent meeting of the Societé Vaudoise de Médecine, Dr. Dufour, of Lausanne, read notes (*Revue Médicale de la Suisse Romande*, 1889, No. 6, p. 387) on three successive cases of detached retina in which he had tried a method of treatment, introduced by Dr. Schoeller, of Berlin. The method consists in injecting a drop or two of tincture of iodine into the vitreous body, in order to excite an adhesive inflammation. In every one of Dr. Dufour's cases, the injection was rapidly followed by a striking improvement of the patient's vision. The amelioration proved to be permanent, as the author stated at a subsequent meeting of the society (*vide ibid.* No. 9, p. 555). Such beneficial effects of the method are attributed by the author to the "tincture giving rise to a serous effusion, which replaces and fixes the retina to its normal position," which view seems to be supported by the fact that "in about five minutes after the injection, there can be discerned a white exudation pointing to a local action of iodine."

Congenital Absence of Womb and Vagina.—In the Polish weekly *Gazeta Lekarska*, No. 32, 1889, p. 643, Dr. Juljan (pron. Iülïan) Aleksa, of Ianovo, describes the following curious case, presenting several points of interest in both theoretical and practical regards. A healthy and strong, regularly-made, fair-haired, peasant woman, æt. twenty-eight, married eight years, consulted him for sterility and amenorrhœa, expressing at the same time her firm belief that everything could be made "all right by making a hole in her virginal membrane." According to her statement, eight years ago, having had no catamenia, but intending to marry her present husband, she had sought advice of an experienced practitioner who, after a careful examination, had declared that she had nothing wrong beyond an occluded hymen, and that "she will be promptly cured by marriage." The doctor's prophecy, however, had not been realised, amenorrhœa remaining as constant as ever, and no children forthcoming. Having patiently waited for eight years, she had ultimately consulted a midwife, who had confirmed the diagnosis of the said practitioner, and directed the woman to Dr. Aleksa, to have her "hymen cut through." On examination, the author found that the patient's breasts were well-developed, and the pubes, genital labia, clitoris and urethra quite normal. On separating the labia, however, the vaginal inlet proved to be occupied by multiple folds of a thickened mucous membrane, while just in front of the navicular fossa there was present a funnel-like depression which, by a forefinger slightly pushing the membrane backwards, could be easily transformed into a *cul-de-sac*, or a rudimentary would-be vagina, with an anterior and posterior wall. A deep puncture with a Pravaz's syringe failed to detect any fluid. Being still under the impression that he had to deal with a case of an occluded and thickened hymen, Dr. Aleksa proceeded with carefully making an incision into the supposed virginal membrane. No cavity, however, could be reached, even after the knife had penetrated full three centimetres deep. It was only then that the author became doubtful in regard to his diagnosis, and having plugged the wound with cotton-wool, decided to make a thorough manual and instrumental examination of the pelvic contents through the rectum and bladder, through either of them and the abdominal wall. Not a trace of the womb or vagina could be detected, the patient's internal genitals being represented only by rudimentary ovaries and apparently hypertrophied Fallopian tubes. Accordingly, to the woman's utter disappointment, he desisted from any further operative interference. A subsequent inquiry elicited that (1) the patient, though having constantly an intense sexual desire, never felt any slightest satisfaction or pleasant sensation from marital intercourse, and even was invariably quite ill for several days after every connection, and frequently fainted during the act. (2) Since her sixteenth year she had been suffering every month from menstrual molimina, such as general malaise, sacral and inguinal pain, dragging sensation about the pelvis, headache, intense tumefaction of the mammary glands, swelling in both groins, œdema of the feet, and hæmaturia. Whether the latter represented a vicarious menstruation, or was caused by some communication existing between the bladder and menstrually bleeding Fallopian tubes, is thought to remain an open question, which cannot possibly be settled otherwise than by a *post-mortem* examination.

[One should think that the very interesting point might be also elucidated by means of an electro-cystocopic examination during catamenial periods, as Dr. Aleksa would probably admit after the perusal of Dr. E. Hurry Fenwick's exceedingly instructive paper in the *British Medical Journal*, May 4th and 11th, 1889, p. 989, a detailed abstract of which may also be found in the Moscow *Meditzinskoïe Obozreniïe*, Nos. 15 and 16, 1889, p. 280.—*Reporter.*]

"Similia Similibus."—Under this title the Polish monthly, *Nowiny Lekarskie*, September, 1889, p. 485, relates the following amusing case, lately published by the *Gazette Médicale de Strasbourg* (1889, May 1st): A male patient, an habitual drinker, was recently admitted to a Strasburg hospital on account of ascites and œdema of his lower limbs in connection with hepatic cirrhosis. One tapping after another was made, but on each occasion the abdominal fluid speedily re-accumulated. On a fifty-second paracentesis, the man insisted on his having the liquid just withdrawn from his belly, and swallowed it at the spot. No re-accumulation took place since that day. "Provided the facts are correct," remarks the editor of our Polish contemporary, "the question arises, how are they to be explained? Should the cure be attributed to the effects of some 'suggestion?' or does the ascitic fluid contain some chemical constituents which up to the present have remained unknown to us?"

On the Diagnosis and Treatment of Chronic Urethritis.—Following Professor V. M. Tarnovsky's teaching, Dr. Alexandr V. Tzvïneff, of Riga (*Proceedings of the Riga Russian Medical Society*, 1889, p. 17), emphatically draws attention to an imperative necessity of determining a precise nature of morbid lesions existing in every individual case of chronic urethritis, such diagnosis being the only means for selecting a rational treatment. The most common lesions occurring in chronic gonorrhœa are these: (*a*) A catarrhal inflammation localised in deeper parts of the urethra; (*b*) papillary granulations resulting from hyperplasia of the mucous membrane; and (*c*) granular vegetations, or peculiar bloodless (or rather, vesselless) protrusions, the degeneration ending in atrophy of the tissues. Every one of the three forms is accompanied by a mucoid or muco-purulent discharge, and may lead in course of time to the formation of strictures of varying size. The stenoses of extreme degrees are usually recognised fairly easily. It is otherwise in cases of milder strictures, which frequently do not give rise to any marked symptoms beyond the so-called *goutte militaire*—that is, a morning-drop of discharge arising from inflammation caused by stagnation of the urine behind a narrowed spot. Without a careful examination, such slight strictures may be easily overlooked, and our treatment accordingly prove a failure, since such means as routinary injections are powerless to remove the lesions of this kind. In view of the facts, Dr. Tzvïneff recommends the examination of every patient suffering from *goutte militaire* by means of a large-sized catheter. If the latter failed to pass into the bladder, a stricture is present. If the instrument passes without any difficulty, one of the three lesions mentioned above must be suspected. The best means for establishing a differential diagnosis between the forms is undoubtedly afforded by an endoscopic examination. The latter, however, requires a considerable skill and special experience. In the absence of the conditions, the endoscope may be, to a certain extent, substituted for by a bulbous catheter. In such cases, where the introduction of the instrument causes a strictly localised pain, and is followed by a few drops of blood, either the *a* form or the *b* must be thought of. In the absence of the pain and bleeding, the cause of the urethral discharge is constituted, probably, by granular vegetations (the form *c*). The treatment varies according to the nature of cases. In those mentioned under *a* and *b*, excellent results may be obtained from injections after Guyot's methods. In cases of granular vegetations, cauterisation by solid nitrate of silver is indicated. Strictures are best treated by a systematic dilatation of the urethra with elastic bougies. The author adduces thirty-one cases of chronic urethritis treated by him during 1887; nineteen of them were speedily cured, but in twelve all means failed until a repeated examination elucidated the actual nature of the lesions present. In eight of the twelve slight strictures, and in four granular vegetations, were found. Under an appropriate treatment all of the patients ultimately recovered.

On the Prophylactic Value of Pulmonary Gymnastics.—Dr. Gaethgens, of Riga, points (*Proceedings of the Riga German Medical Society*, 1889, p. 547) to a great prophylactic value of systematically training the lungs. A thorough ventilation of the organs, more espe-

cially of their apices, requires a certain muscular strength, as well as an erect carriage of the body. Even in persons with a normally-built chest, an habitual defective respiratory action is followed in course of time by a permanent pulmonary weakness, and a decrease in the capacity of resistance towards any pathogenic principles finding their way into the lung. In subjects with an hereditary phthisic predisposition—that is, in subjects with a poorly-made chest, flabby muscles, and lowered power of resistance—the dangers of a defective respiration are still by far greater. In addition, in either of the categories, the dangers are not limited to a train of pulmonary diseases, but also include various anæmic or chlorotic disturbances, as well as nervous affections. Hence, the pulmonary gymnastics are of a paramount practical importance, and should be systematically resorted to in all children, and that at a possibly early age. In other words, every child's respiratory organs should be methodically trained by means of certain physical exercises, consisting mainly of steady and deep respirations in free air, the child standing or walking in a perfectly upright position. Once the habit of thoroughly ventilating the lungs has been firmly established by a training course of this kind, the child unconsciously or instinctively retains it for life. The author is about to initiate the gymnastic courses of this sort on a large scale.

On the Physiological Action of Sulphonal.—In the *Vestnik Obshtchestvennoi Highieny, Sudebnoi i Praktitcheskoi Meditziny*, July, 1889, p. 1-10, Professor Serghei A. Popoff and Dr. Vladimir I. Podanovsky, of St. Petersburg, publish a paper on their experimental researches concerning the physiological effects of sulphonal. The main results of the experiments (on frogs) may be summed up as follows:

1. Sulphonal acts in the first instance on the respiratory process, gradually retarding it, and when injected in large doses (0.02 gramme and more; 0.03 gramme doses prove almost invariably lethal in frogs), causing a complete arrest of breathing.

2. The drug powerfully inhibits voluntary movements, which is dependent solely upon its direct action on the motor centres (since both muscular and motor nerve irritability remains intact, even during the stage of a complete prostration preceding the animal's death).

3. It markedly depresses both tactile and pathic sensibility, acting on the peripheral nerve endings. On keeping the frog's leg in a 1 per cent. solution for from two to five minutes, the sensibility of the limb disappears tracelessly, while it remains normal in all other regions of the animal's body.

4. Sulphonal lowers the reflex action, which is mainly dependent upon its inhibitory effects on the spinal cord, but partly on its anæsthetic action on the peripheral sensory nerves.

5. The action of the drug on the cardiac muscle is relatively weak. Still, large doses produce a gradual retardation of the cardiac action, while lethal ones arrest the heart in diastole. The retardation and diastolic arrest seem to be caused by a direct action of the drug on the cardiac muscle and motor nerve apparatus.

[The authors' results can scarcely afford a conclusive evidence in favour of sulphonal's "freedom from any dangerous accessory effects," to which Professors Baumann and A. Kast have once drawn the attention of the profession.—*Reporter.*]

V.—PUBLIC HEALTH.

Case of Paralytic Rabies in a Patient Inoculated by M. Pasteur. Related by Dr. V. Rascol, with comments by Prof. Michel Peter, accompanied by the following letter to the Editor of the *Journal de Médecine de Paris:*

SIR,—I have the honour to submit to you, and to M. Pasteur at the same time, the following case, fatal after the anti-rabic treatment at the Pasteur Institute. I have thought it well to postpone this communication until the rumours attributing the death of Rascol to the preventive inoculations had subsided. The electoral excitement has sufficed for that; but, notwithstanding, there still exists an impression upon the popular mind that these inoculations are not free from danger. The opinions expressed by yourself in opposition to those of M. Pasteur, have determined Dr. Vergnard and myself to submit to you, for the elucidation of so grave a question, the following case, the importance of which is indisputable. The interest which attaches thereto, in point both of humanity and of science, is so great that the obligation should be imposed upon every physician to contribute to the elements of its determination.

Murat (Tarn), Sept. 25th, 1889. (Signed) VICTOR RASCOL, D.M.

The case is as follows:

During the month of February, 1889, the occurrence of numerous mad dogs was noticed. One of these bit several other animals of the same species. On the 20th February it bit two men and a horse. He attacked his first victim on the right leg. The bite traversed two pantaloons, and lacerated the cutaneous surface. The wound was healed by the end of twelve days. His second victim was a rural postal messenger, who was bitten on the right leg, through two pantaloons, of which the external were torn, while the marks of the teeth were left on the skin, which was grazed. A few drops of blood had oozed and formed coagulum.

The horse died on the 11th April, not having been seen by a veterinary. The symptoms, which were regarded as rabies, were violent agitation, rearing, and striking against the manger and rack.

The man first bitten experienced no ill effects. It should, however, be stated that he went a pilgrimage to the chapel of a saint who enjoys the special reputation of preserving from rabies.

The messenger was sent to the Pasteur Institute on March 6th. He began the treatment on the 9th, and continued it until the 23rd (fourteen days). He returned to his work on the 26th. On the 9th and 10th of April he was engaged at hard labour in the country, which obliged him to remove his waistcoat, though he felt the cold on his shoulders and body, in spite of which he continued his work until night. On his return home he experienced no effects from the cold. On the 11th April the factor Rascol, passing through the village of Montaigut, met the body of the horse being carried away that had been bitten on the same day as himself, and had died that morning. On this day Rascol experienced a greater sense of fatigue than on other days of his journey. From this time he became sad, morose, depressed. He lost his appetite and complained of severe headache. He took a dose of castor oil, which acted on his bowels and somewhat relieved his head. Nevertheless, the general feeling of malaise remained, with a sense of extreme lassitude, with tightness in the throat and difficulty in swallowing.

I was called to him on the afternoon of the 12th inst. His face was animated, and he complained of the sense of constriction in the throat, which, however, did not prevent his swallowing small quantities of vermilion and ptisan. The tongue was normal; the uvula was enlarged; the surface of the pharynx red and glossy as far as could be seen. He complained that his throat and mouth were coated with a thick mucus secretion, of which he could not free himself, notwithstanding that his efforts to do so provoked vomiting. He attributed to this mucus the difficulty of swallowing, but his family observed that he had always a very narrow swallow. The eyes were bright and fixed upwards, with a convulsive stare, and intolerance of light. Respiration normal, though sighing at times. Auscultation detected nothing abnormal in the respiratory sounds. The pulse was normal; the temperature also normal.

The patient complained of general debility, which rendered it impossible for him to turn in bed. He moved his arms and legs with difficulty. There was a complete loss of muscular power except in the heart, the beats of which were regular and possessed sufficient impulse. He complained of severe headache, and a feeling of indefinite pains in various parts of the body, *principally in those parts where the preventive injections had been practised.* The bladder was not distended, though on two occasions he was unable to void urine. General frictions were employed, with tincture of quinine and limiment de rosea; over the region of the bladder friction was made with camphorated oil; on the neck, with belladonna ointment; bromide of potassium was given in draughts.

Rascol related in detail his journey to Paris, and the treatment he had undergone in the Pasteur Institute. His recollections were not in exact accord with the card that had been given to him, and which he had forwarded to me. I carefully avoided alluding to the horse's death, and he observed the same course; nevertheless he was preoccupied. I took an opportunity, when speaking of his bite, to explain that "the dog's tooth having been wiped in its passage through the first pantaloons, and not having pierced the second pair, the bite could not possibly have transmitted anything."

I have omitted to state that the dog who had been examined *post-mortem* by a veterinary surgeon, who pronounced it 'suspected of rabies.'

On April 13th we saw the patient with Dr. Vergues. The face was more animated, redder, the eyes merry bright, directed upwards; the pupils were normal. Respiration difficult, sighing, but without any morbid sound. Pulse normal. Complete want of muscular power, except in the arms, which were moved with less difficulty. The lower limbs motionless and insensible. Not any painful point was to be found in the vertebral column. Difficulty in swallowing increased, the mucous secretion accumulated, and breathing and speaking became so much interfered with that it was not easy to understand what he said. A catheter drew off two litres of urine—pointing to paralysis of the bladder.

The same treatment was continued. The patient became the prey to most distressing ideas; during the night he had demanded the last rites of religion, and gave directions as to his funeral. On the 14th he died asphyxiated, about 6 a.m.

In what pathological category can we place this case? Must we admit a special factor in its etiology?

Here is my reply:

It is very evident that we have here to deal with a case of rabies. 1. The period of incubation is almost classical, forty-three days, on the assumption that the rabies was transmitted by the dogs; thirty-three days if the rabies had been given in the laboratory by a rabbit. 2. The outbreak of these accidents took place as the result of an acute motion (the sight of the dead body of the horse, bitten simultaneously). 3. There occurred the bulbar disturbances (of the pneumo-gastric and glosso-pharyngeal) of rabies.

This rabies was modified: 1. The phenomena of paralysis replaced those of convulsion (paraplegia, paralysis of the glosso-pharyngeal; finally of the pneumo-gastric with asphyxia). 2. Intelligence remaining unimpaired to the last. We have here the same phenomena observed in the unfortunate Reveillac, of Paris, in the case observed at Armeil, and in another case inoculated at Dunkirk, also in Née, of Arras.

Lastly, the sinster phenomenon which casts a lugubrious light on the question, the premonitory pains were not experienced at the line of the punctures as in the case indicated. Your patient then died, I do not hesitate to say, of rabies of the laboratory. Many other cases have passed undetected or misunderstood. Death has been attributed to some unusual neurosis, or to pneumonia; to pain at the points of inoculation; to rapid dyspnœa and asphyxia; to a still strange form of pneumonia without expectoration, and without fever. On the other hand, the indifference, the interest, or the fear of responsibility to be incurred by the physicians who have been weak enough to send persons bitten to the Institute, have all contributed to ensure silence, for a time, on this subject.

To sum up, we may say of the three subjects bitten by the same dog:

One, the horse, having no protection of clothing, died of convulsive rabies, contracted from the dog.

In the case of the other two, the bites were made through double clothing. Of these, one was not inoculated, and remained healthy seven months later. The other man, thanks to the care of the postal administration, was inoculated, and manifested the symptoms of paralytic rabies (the rabies of the laboratory), thirty-three days subsequently. The conclusion is self-evident.

P.S.—It is necessary in comparing Rascol's case inoculated and rabid (at the same time that his fellow sufferer was not inoculated, and did not become rabid), with that of [1] W. alone inoculated, and alone became rabid; while his companions, who were not inoculated, continued in good health. It must be observed, in aggravation of W.'s case, that the bite was inflicted through his garments.

(Signed) PROF. PETER.

The Spirit of the Societies.

West London Medico-Chirurgical Society.—This Society was opened by an address from the President (H. Campbell Pope, M.D.), which will be found at page 654.

Specimens were shown by Mr. Keetley of loose cartilages removed from two knee-joints, and a portion of a kidney crushed off by a waggon wheel, and removed through a lumbar incision.

Mr. Percy Dunn also showed some recent additions to the Museum of the West London Hospital.

* * * *

Obstetrical Society of London (A. L. Galabin, M.D., president). **A Contribution to the Anatomy of the Pelvic Floor.**—Dr. G. Ernest Hermann in this paper detailed measurements which showed the great normal variations in the conformation of the parts which formed the floor of the pelvis. He showed that projections of the pelvic floor varied from none at all to as much as two inches, and that in healthy multiparæ the distance between the coccyx and anus, the length of the perineum, the distance between the fourchette and the symphysis pubis, and the length of the vagina, were subject to wide variations. Dr. Hermann pointed out that since these variations existed in healthy multiparæ, peculiarities observed in parous women should not be assumed to be changes due to childbearing, unless it had been ascertained that they were not present previous to pregnancy. He next pointed out the clinical importance of these anatomical variations in their bearing on the liability to rupture of the perineum, and to prolapse, the adjustment of pessaries, and some forms of dysparennia and sterility were pointed out.

* * * *

British Gynæcological Society (Dr. Macan, president, October 9th).—This was the first meeting of the society after the recess.

Fibro-Cystic Tumour of Uterus.—Dr. Bantock showed a specimen of a tumour which he had removed, and he thought interesting from a pathological point of view. It had been in existence about eight years. It dragged on the uterus when moved. He had diagnosed fibroid of the uterus, probably with pedicle. When he opened the abdomen the appearance seemed to confirm this view, but on pressing with a finger he found fluctuation, and on tapping it he withdrew seven and a half ounces of fluid containing cholesterine. He found that it had a pedicle not at all connected with the uterus, and he thought it must be ovarian, a degenerated cyst for example. The pedicle was attached to the right broad ligament, at the corner of the uterus. The patient was a cook, single, and thirty-five years of age. He had operated on October 3rd, and she is now convalescent.

Epithelioma of Clitoris.—Dr. Edis showed a specimen which he had removed from a single woman, æt. forty-three. Two years before she had complained of severe irritation about the meatus urinarius, sometimes accompanied by pain on passing water, which, however, was not unduly frequent. During the last three weeks there had been a slight discharge from the growth. He caught hold of it with a pair of vulsella forceps, and then removed it in its entirety by means of a Paquelin cautery, being careful to avoid touching the tissues that were implicated. The hæmorrhage was nothing to speak of. The wound was stuffed with iodoform gauze, and the patient made a good recovery.

Adjourned Discussion on Dr. Dolan's Paper.—Dr. Bantock said he hoped that they had all a printed copy of it before them. He said that Dr. Dolan had approached the subject in a very philosophical spirit, discussing the matter, with one or two trifling exceptions, in manner devoid of prejudice. He then reviewed the views put forward by Dr. Dolan in diagnosis. Alluding to the author's expression, "that instrument of destruction the uterine sound," he said he could not conceive why Dr. Dolan had singled out the sound in this way, for he (Dr. Bantock) considered it a most valuable instrument for diagnostic purposes. Of course it must be used carefully and intelligently, but he would be very sorry to be deprived of it. When injury followed its use, the inference was that it had been used unskilfully or in improper cases. He did not agree with him in his condemnation of pessaries in the treatment of displacements, or at least some of them, although he says he is supported by some of the oldest gynæcologists in England and Ameriea. Dr. Dolan, however, confined himself to the treatment of flexions of the uterus, but he (Dr. Bantock) had always preached the doctrine that a pessary was no good in cases of flexion, however useful it might be in versions. If Dr. Dolan had been in the habit of treating flexions by means of vaginal pessaries, he could readily understand how he had arrived at his conclusions. He observed that it was really remarkable how little this subject was studied, for he might say with Dr. Dolan that he had had a great deal of experience in removing pessaries, but he had also some experience in applying them. A pessary was not intended to replace a uterus, but to retain it in position. He observed that Dr. Dolan seemed to favour some of the more risky operations which had been invented—removal of the appendages, shortening of the round ligaments, pereonorrhapy, etc. So far as the removal of the tubes was concerned, and in respect of the restoration of the perineum, he might be disposed to agree with him, but in his opinion shortening of the round ligaments was dangerous, and without effect on the position of the uterus, while the proposal to suture the fundus to the parietes was an idea which had not been ratified by experience. Passing on to discuss Dr. Dolan's remarks on the relations of specialists and the general practitioners, he recalled an instance in which a lady, who fully intended to place herself under his care, had consulted him, presenting a letter from her ordinary medical attendant with the previous history of the case. Finding the lady intended to remain under his treatment he consequently wrote to her medical man to that effect, and received in return a letter of violent abuse accusing him of having taken his patient, and asking him if he would consent to arbitration. To this question he replied that he would gladly submit to arbitration, and probably this satisfied the medical man, for he had heard nothing more from him on the subject. He pointed out that the medical man was entirely in the wrong.

[1] This case is reported in *Journal de Médicin de Paris*, 6th Oct., 1889.

Medical Miscellanea.

THE subject of our next illustration will be Dr. Freeman, Mayor of Bath.

* * * *

Mr. Miller, M.P., has given £2,000 to the Felixstowe Convalescent Home.

* * * *

A very handsome sum has been collected towards the funds of the Scarborough Hospital and Dispensary by a large number of ladies, who took charge of stands in the most prominent parts of the town.

* * * *

The proprietor of *Tit-Bits* has offered to distribute the sum of £10,000 among the hospitals of England if the average circulation of his journal for the year 1889 shall reach half a million copies weekly.

* * * *

Dr. Spottiswoode Cameron has been elected Medical Officer of Health for Leeds. He was for nearly twelve years Medical Officer of Health for Huddersfield.

* * * *

The muzzling orders are still imperfectly carried out. Some of the County Councils insist on having all dogs muzzled; others reject the order. Muzzling to be effectual should be universal.

* * * *

Female medical education at Edinburgh has received an impetus from the formation of an association for its promotion. It is supported by some well-known men in the profession.

* * * *

We regret to have to announce the death of Dr. Protheroe Smith, which took place on September 29th, at his residence, 24, Park-street, Grosvenor-square, in his eightieth year. Dr. Smith was the founder of the first hospital for women.

* * * *

Mr. Tom Mason, of Portwood, has left £3,000 to the Stockport Infirmary. Mr. D. Cullimore, barrister, has bequeathed £1,000 to the County Infirmary, Wexford; and the poor of the village of Taghmon, co. Wexford, have received £8,000.

* * * *

A public house map of the borough of Leeds has just been issued. There are 355 fully licensed houses, 422 beer houses, and 362 off-licensed shops, making a total of 1,139 houses and shops in which intoxicants are sold. The population is 350,000, and it is calculated that Leeds expends on alcohol £1,213,000 per annum.

* * * *

Dr. Hammond (Nuneaton) was presented on September 26th with an illuminated address and a purse of £100 guineas. Mrs. Hammond was also presented with a massive gold bracelet by a deputation of ladies, with an expression of regret at the departure of Dr. and Mrs. Hammond from the town.

* * * *

The first meeting of the Medical Society was held on Monday, October 21st. The Lettsomian lectures will be delivered during January by Mr. Edmund Owen, on subjects in connection with the surgery of infancy and childhood. The annual oration will be given by Dr. A. E. Sansom on May 6th.

* * * *

We regret to announce the death of Mr. Richard Power, which took place on October 2nd. Mr. Power was for many years the much respected officer of H.M. Convict Prison at Portsmouth. Two months ago he was promoted to the Governorship of Woking Female Convict Prison.

* * * *

The annual meeting of the medical officers of health was held at the Guild Hall, Worcester, on Saturday, Sept. 28th (Professor Corfield, president, in the chair). Dr. H. Swell read a paper on the "Actual and Probable Effects of Recent and Prospective Legislation upon Medical Officers of Health." Mr. Taylor (Liverpool), Mr. Willis Bond (Worcester), Dr. Strange, Sir H. Ackland, Dr. Mitchell, joined in the discussion. Dr. Whitelegge, Medical Officer of Health for the West Riding, read a paper on the "Best Means of carrying out the Notification of Infectious Diseases Act." Numerous speakers took part in the discussion.

The Northumberland and Durham Medical Society opened its session on October 5th with an address by Mr. Lawson Tait, the full text of which we publish at page 645, "On Ectopic Gestation." Dr. Murphy, Sunderland, is the president. After the meeting the members and guests (150) dined at the assembly rooms.

* * * *

We regret to have to record the following deaths after treatment at the Institute Pasteur:

CASE XIII.—J. B. Sattraux, of Bourgival, æt. fifty-four, bitten on July 5th, 1889; treated from the 5th till 26th July. Died of hydrophobia August 10th, 1889.

CASE XIV.—M. Claudel, Nancy, bitten July 8th, 1888. A year afterwards he felt at the place where the inoculations were made a kind of intense burning. Died of hydrophobia August 10th, 1889. The patient was attended by Dr. Jacob, of Nancy, and an autopsy was made by MM. Fellz and Baraban. Some rabbits were experimented on, which died on the thirteenth day after inoculation.—*Journal de Médicine de Paris*, October 6th, 1889.

* * * *

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—At the first meeting for the session, held on October 4th, the following gentlemen were elected office-bearers for 1889-90:—*President:* Dr. William Macewen. *Section of Medicine.—Vice-President:* Dr. J. Wallace Anderson. *Council:* Dr. Hugh Thomson and Dr. W. G. Dun. *Secretary:* Dr. Geo. S. Middleton. *Section of Surgery.—Vice-President:* Dr. David W. Knox. *Council:* Dr. W. J. Fleming and Dr. J. C. Renton. *Secretary:* Dr. John Barlow. *Section of Pathology.—Vice-President:* Dr. W. T. Gairdner. *Council:* Dr. H. Rutherford and Dr. Joseph Coats. *Secretary:* Dr. T. Kennedy Dalziel. *Section of Obstetrics.—Vice-President:* Dr. W. L. Reid. *Council*: Dr. M. Cameron and Dr. Samuel Sloan. *Secretary:* Dr. Lawrence Oliphant. *—Treasurer:* Dr. Henry E. Clark. *General Secretary:* Dr. Walter Downie.

Correspondence, Notes, and Queries.

Communications, Books, etc., should be addressed directly to the EDITOR, "*The Provincial Medical Journal,*" *Horton House, Halifax.*

Matters of business should be addressed to the Publisher, at the Offices, 10, *Friar Lane, Leicester.*

We cannot undertake to return rejected MSS. unless stamps sufficient for their postage are enclosed.

We shall be glad to receive reports of Medical Vacancies, Appointments, Meetings of Societies, etc.

Papers containing passages for consideration should be marked.

Correspondents must please attest their communications with their proper name and address (not necessarily for publication).

Contributions must be written on one side only of the paper.

MSS. intended for publication to be sent in not later than the 16th of the month.

The insertion of any letter in these columns cannot be taken as necessarily indicating our adhesion to the views or statements therein expressed. The same remark applies to articles to which a name or nom-de-plume is attached.

PROPOSED SCALE OF FEES FOR THE PUBLIC MEDICAL SERVICE OF ENGLAND.

FEES TO BE PAID BY WAGE EARNERS WHO ARE MAKING UNDER 45*s.* PER WEEK PER FAMILY, FROM ALL SOURCES. ALL PAYMENTS TO BE IMMEDIATE.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—The following scale is submitted to the profession:

MEDICAL FEES.—Visit at branch: 2*s.* for the first, and 1*s.* for subsequent visits during the same illness. or 4*s.* per week in advance for five visits (with or without prescription).

Visit at patient's home: from 11 a.m. to 6 p.m., 2*s.*; from 6 p.m. to 11 a.m., 5*s.* with or without prescription).

Consultation at patient's home before 6 p.m., 10*s.* 6*d.*; after 6 p.m., 20*s.* for each doctor.

Visiting a second, third, or fourth patient at the residence of the first patient treated, 2*s.* each for the first day visit, and half this fee for subsequent visits.

When the patient lives more than two miles from the doctor's residence, and when he has to visit at this patient's home, the doctor may charge the cost of cab for out and home journey.

	£	s.	d.
Remaining all night with a patient	1	1	0
Remaining with a patient after the first half-hour, per hour, or part of an hour	0	5	0

Not more than two visits a day to be paid to a patient unless he or his relatives request further visits to be paid.

LETTERS AND CERTIFICATES OF ALL KINDS.—2*s.*, exclusive of postage.

VACCINATION.—With human lymph, including subsequent inspection and filling up certificate, 2*s.* 6*d.*

With calf lymph, ditto, 3*s.* 6*d.*

OBSTETRIC FEES.—Abortion or premature labour (with three subsequent visits)

	1	0	0
Normal labour (including three subsequent visits)	1	5	0
Labour, with forceps	1	10	0
,, ,, turning	1	15	0
,, ,, craniotomy	2	2	0
,, ,, transfusion	2	2	0
Anæsthetic at any of the above	0	7	0
Removal of after-birth without conducting confinement	1	0	0
Dilatation of cervix with tents, bags, or instruments	0	10	0
Help, in connection with difficult labour, from another doctor	1	0	0
Induction of premature labour, and completion of such labour	1	15	0
Treatment of severe *post-partum* hæmorrhage	0	10	6
Treatment of *ante-partum* hæmorrhage (exclusive of confinement fee)	0	7	6
Examination of wet nurse	0	2	0
Operation for recent rupture of perineum	0	5	0
Cæsarian operation	2	10	0
Irrigating vagina or uterus	0	2	6

GYNÆCOLOGICAL FEES.—Treatment of minor affections of uterus

	0	2	0
Removal of small tumours from vulva, vagina, or cervix	0	3	6
Introduding pessary (pessary included)	0	2	0
Curetting interior of uterus	0	7	0
Operation for atresia of vulva, vagina, or cervix	0	7	0
Operation for imperforate hymen	0	7	0
Operation for old rupture of perineum	1	1	0

POST-MORTEM FEES.—External examination of dead body

	0	7	6
Post-mortem examination, partial	1	0	0
,, ,, complete	2	2	0
Written statement regarding *post-mortem* examination	0	10	6

SURGICAL FEES.—Passing catheter

	0	2	0
Removal of small tumour 3*s.* 6*d.* to	0	10	0
Removal of tonsils, or enlarged glands	0	10	0
Removal of nævus, tenotomy, circumcision	0	10	0
Harelip, operation for	0	10	0
Reduction of hernia	0	10	0
Removal of ingrowing nail, or opening of abscess	0	2	6
Treating simple wounds, burns, or scalds	0	2	0
Treatment of simple or compound fracture or dislocation (apparatus included) of the arm	0	15	0
,, ,, ,, ,, ,, ribs or clavicle	0	12	6
,, ,, ,, ,, ,, thigh or leg	1	10	0
,, ,, ,, ,, ,, jaw	0	10	0
Amputation of finger or toe	0	10	0
Testing sight (glasses not included) per visit	0	3	6
Operation on eyelid or eye from 5*s.* to	1	0	0
Treatment of disease of the ear	0	2	0
Operation on ear by knife or snare	0	3	6
Washing out of stomach	0	5	0
Chloroform or ether administration	0	5	0
Consultation at branch	0	7	6
Consultation at patient's home (see above)	0	10	6
Testing urine, chemically and microscopically	0	2	0
Removal of nasal polypus	0	5	0
Removal of foreign body from ear or nose	0	2	0
Tracheotomy	0	12	6
Skin-grafting	0	2	6
Paracentesis of the thorax or abdomen	0	7	6
Tapping hydrocele	0	5	0
Operation for fistula *in perineo*	0	7	6
Operation for internal hæmorrhoids	0	12	6
Operation for imperforate anus	0	10	6
Cupping, dry or wet	0	5	0
Venesection	0	7	6
Leeching	0	2	6
Washing out the bladder or bowel	0	3	6
Seton, or issue	0	2	6
Administering an enema	0	2	6
Wet packing	0	2	6
Application of constant or induced current	0	3	0
Stretching or stitching a nerve	0	10	6
Arresting arterial or venous hæmorrhage	0	2	6
Removal of foreign bodies from eye or throat	0	2	6
First treatment of a sprain of upper or lower limb	0	2	6
Operation for paraphimosis	0	10	6
Injecting bowel with air or fluid for intussusception	0	4	6
Reduction of strangulated hernia	0	10	6
Operation for strangulated hernia	1	0	0
,, rectal ulcer	0	2	6
,, ,, fissure	0	2	6
,, ,, stricture	0	7	6
Extraction of foreign body from urethra	0	3	6
Treatment of urethral stricture by bougie, per sitting	0	2	6
,, ,, operation	0	15	0
Puncture or aspiration of bladder	0	4	6
Crushing stone in the bladder	0	10	6
Aspiration of joints or cavity	0	4	6
Strapping testicle	0	2	6
Extirpation of testicle	0	10	6
Plugging the nostrils	0	4	6
Measuring and fitting felt or plaster jacket	0	3	6

Doctor's assistance at an operation at patient's home or at branch, equal to that mentioned as the full surgical fee.

Excision of the breast	0	10	0

In case the fee for an operation is not mentioned in the above list, such fee shall be fixed at a meeting of the branch committee, at which at least three-fourths shall be present. Scale of fees to be revised every fifth year. The above scale of fees refers to operations performed before 7 p.m. After that hour an extra half fee may be charged.

DENTAL FEES.—Extraction per tooth

	0	1	0
Extraction each extra tooth	0	0	6
,, under gas	0	2	6
,, ,, and each extra tooth	0	0	6
Stopping with amalgam, per tooth	0	2	0
,, ,, gold ,,	0	4	0
Extractions under ether or chloroform	0	12	6
Artificial tooth, with vulcanite plate	0	4	6
,, ,, ,, ,, and each extra tooth	0	2	0
Scaling teeth	0	2	6
Examination of all the teeth without operation	0	2	0
Small operations on the gums, or removing tumour	0	3	6
Regulating apparatus for deformed jaw or teeth, made of tin or vulcanite	0	7	6

Visits to patients' home, the same as medical fee for for such

Cleansing and stopping of root, the same fee as stopping of tooth

Administration of ether or chloroform by doctor for dental operation	0	7	0

CHEMIST'S CHARGE.—4*d.* per prescription.

In case more than one prescription is dispensed at one time for the patient, such as a mixture, pills, ointment, or liniment, the sum of 3*d.* will be charged for each. No prescription to be renewed for the patient by the chemist until the patient has been again advised by the doctor. No copies of prescriptions to be given by the chemist to the patient. All prescriptions to belong to the doctor who wrote them.

I have drawn up this scale of fees after prolonged deliberation, and after having taken the opinions of doctors, dentists, chemists, and employers of labour. The scale is drawn up greatly in favour of the wage earner, and the fees quoted are much below those paid by the Poor Law. I would suggest that the scale of surgical, obstetric, gynæcological, dental, and vaccination fees, and those for letters and consultations, be adopted as the scale for the provident scheme, while the fees relating to visits and medicine be considered separately.

In drawing up a table of payment for Provident Dispensaries, I would suggest than an "Age Table" be used as in other insurances. I would charge every member 6*d.* per month, and place the different rate of payment on the "entrance fee;" for, though the entrance fee would be paid yearly, each member would require to be examined by one of the medical staff before admission, and for this he would be paid 2*s.* out of the Hon. Members' Fund.

The scale of yearly entrance fees would be—

	s.	d.
From the age of 0 to 8 years	2	0
,, ,, 8 to 16 ,,	1	3
,, ,, 16 to 40 ,,	0	6
,, ,, 40 to 55 ,,	0	9
,, ,, 55 to 70 ,,	1	0
,, ,, 80 and upwards	2	6

When the entrance fee exceeds 1*s.* the balance to be paid from "Hon. Members' Fund." One penny will be charged for each separate prescription. A levy of 1*d.* per month would be placed on each benefit member, so as to help in defraying management. The fees for vaccination, surgical or obstetric operations, and confinements, would be the same as those of the Public Medical Service (see above). The sum subscribed by honorary members would be one-third the amount paid by benefit members. I would fine any doctor or dispenser 5*s.* who supplied any benefit member with treatment or medicines who was in arrear with payments. Members would enter into benefits two months after joining. In case of confined illness, or infirmity of old age, a yearly entrance fee of 5*s.* would be charged, plus the 6*d.* monthly and levy.

I think the above plan of placing the different scale of payments on an annual entrance fee is better than making different monthly payments for each member. It will be less cumbersome, and will induce members to stay. If the hospitals turn away at least 42.32 per cent. of their present out-patients, the provident system would soon be a success. London—to begin with—would have a total of 700,000 benefit members in the first year.

Supposing we had a provident society of 1,000 benefit members, the following would give a fair idea of the expenditure :—

	£	s.	d.
Rent and taxes	36	0	0
Coal and gas	3	0	0
Printing, postage, and stationery	12	0	0
Drugs, bottles, bandages, instruments, etc.	25	0	0
Examination fees to medical staff	100	0	0
Cleaning of Branch	5	0	0
Dispenser, including residence at Branch	65	0	0
Commission on collection of members' payments, five per cent.	15	0	0
Part payment of entrance fees	12	10	0
Furnishing Branch	15	0	0
Salaries to medical staff	350	0	0
	£637	10	0

The income of such a branch would be :—

	£	s.	d.
Sale of members' books, 2*d.* each	8	6	8
Fines	1	0	0
Sale of drugs	20	6	8
Levy on benefit membets	50	0	0
Entrance fees at 1*s.* 3*d.* each (average)	50	0	0
Monthly payments from Branch members	300	0	0
Subscriptions from honorary members	214	16	8
Total income	£644	10	0

thus leaving a balance of £7.

The above sample balance sheet shows that with 1,000 members we should repuire an income of £637, and to meet this there would be a payment of £429 13*s.* 4*d.* from benefit members. A third of the latter sum must, therefore, come from honorary subscribers, that is, £214 16*s.* 8*d.*

As regards the amount this would give to the medical staff of, say, four doctors, we should have from

	£	s.	d.
Examination fees from honorary subscribers	100	0	0
Part entrance fees	12	10	0
Entrance fees from benefit members	50	0	0
Monthly payments	300	0	0
	£462	10	0

This would give on an average £114 12*s.* 6*d.* to each doctor, and, giving five visits to each member, this would make a fee up to 1*s.* 10*d.*

The average yearly payment by each benefit member would be :—

	s.	d.
Average yearly entrance fee	1	0
Member's book	0	2
Twelve monthly subscriptions	6	0
Levy	1	0
Five prescriptions per annnm	0	5
	8	7

This is about 8d. per month : 2d. per week, or 1 farthing per diem, each benefit member would cost the society 12s. 10d. per annum, and would pay 8s. 7d. of this himself.

Some, especially employers of labour, will no doubt object to pay part, but such must be let know that medical men have gone as far as they can in supplying medical aid on a charitable basis. The limit of unpaid medical service has been reached. I do not think 1s. 10d. is too high a fee for a night visit. As at present conducted, the vast majority of provident dispensaries are supplying medical aid to very well-to-do people for a very few coppers a month. It is not too much to hope that as wages have gone up so much during the last few years, the industrial classes will see their way to cease asking for more medical charity. True charity begins at home, and, for my part, I cannot see why one deserving class of society should starve themselves, their wives, and children, and should leave them depending on one or two benevolent medical institutions so that well-to-do people may have more money to spend on luxuries. I am not now speaking of hospitals, where true charity should always resign, but of a class of the community who would be insulted if they were told they were, in a medical sense, paupers, and depending on the benevolent actions of others. I am speaking of a provident plan which should be as little depending on charity as are our Oddfellows' and Foresters' societies, or the German working classes under their compulsory plan of insurance against sickness.—I am, etc.,

ROBERT REID RENTOUL.

Liverpool.

VOTING BY PROXY.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—At the last annual meeting of the British Medical Association at Leeds, Dr. Erskine and I had given notices of motion that voting by proxy should be allowed at general meetings of the Association. Finding, however, that in order to give this power the Articles of Association must be altered, we withdrew our motions, because any alteration in the Articles of Association has to be made at a special general meeting called for the specified purpose, and the alteration has to be confirmed at a subsequent general meeting, a majority of three-fourths being required. Wishing to test the opinion of members as to the proposed change, I drew up a requisition asking for a special general meeting of the Association to be called for the purpose of allowing voting by proxy at general meetings. Such a requisition must have the names of 100 members attached to it, and I have already obtained the greater part of this number of signatures. The requisition will be presented when it is thought a suitable time for doing it.

With regard to the desirability of allowing voting by proxy, it is the only way in whlch the opinion of the whole Association can be taken on any subject. At present only those who are able to attend the general meetings in person have an opportunity of expressing their opinion. It is true members can exert an indirect influence through the branches and their representatives on the Council; but even this remote influence is denied to that very large section of the Association —the "unattached" members. All these unattached members have no voice whatever unless they attend the general meetings.

Some of us hope that—in spite of strong opposition—we may be able to induce the Association to use its powerful influence in promoting much-needed reforms, and removing the gross abuses which discredit the medical profession. In order that such action may be productive of beneficial and permanent results, it is quite necessary that the humblest in the profession should have a direct voice. If every member of the Association is not fit to have a vote, then the Association should take steps to prevent the admission of unfit members, not to the Association only, but also to the medical profession. There is a large number of members of the Association who occupy the position of assistants to older or more fortunate medical practitioners. These are seldom attached to any branch of the Association, because they have no fixed abodes, and it is usually quite impossible for them to attend the general meetings of the Association. Who is to defend their interests? I think, moreover, that a strong argument in favour of a step which will give increased power to individual members of the Association is afforded by the attempts recently made to force the hands of the Association by threats of wholesale resignations, and by other unconstitutional means. I was myself present at a meeting of the metropolitan branch, which—from its position—exercises a powerful influence on the whole Association, when a member coolly informed the meeting that unless a certain resolution was passed he would hand in the resignations of over 100 eminent London doctors. Now, is it right that our Association should be swayed by whatever faction or party happens to be in the ascendant in London medical circles? If every member of the Association had a direct voice in its management, there would be no fear of its being made the sport of metropolitan jealousies and rivalries.

Some, however, are anxious—above all things—that the Association should be purely scientific, and should not attempt to better the condition of the medical profession. These, of course, will oppose voting by proxy, for there can be little doubt that the majority of medical men feel that the time has come for a sustained effort to make the medical profession something like the noble profession which October orators, interested in maintaining optimistic views, are so fond of depicting it.

You are good enough to offer your columns for the ventilation of the question of voting by proxy in the British Medical Association, and I trust that those who intend to oppose this reform will publicly give their reasons for doing so. It must be admitted that there is at least a *primâ facie* case in its favour. The requisition to which I have alluded above is thus worded :

"We, the undersigned members of the British Medical Association, hereby request the Council of the Association to convene an extraordinary general meeting of the Association, for the purpose of adding to or altering the Articles of Association, so as to allow voting by proxy at all general meetings of the Association, and to provide for the circulating of unstamped proxy papers with the copies of the journal, at a convenient time before such general meetings; and also to make any other such changes in the Articles of Association or By-laws as shall appear to the meeting advisable on account of the admission of voting by proxy."

I shall be glad to append the name of any member of the Association who sends me his signature, with qualification and address, written on a clean sheet of paper.—I am, yours,

Highgate, London, N. HUGH WOODS, M.D.

ON THE REMOVAL OF RENAL CALCULI BY TOXIC DOSES OF BELLADONNA.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—An article on this subject, by Dr. W. Murray, in the last issue of the PROVINCIAL MEDICAL JOURNAL, is my reason for remarking on the uncertainty of the British Pharmacopœial tinctures and extracts, which are yet, for the most part, unstandardised.

Dr. Murray remarks that "We may begin with a forty-drop dose of the tincture, and repeat it every two hours, increasing or diminishing the dose according to its effect on the patient." Now it is the experience of every practical therapeutist that the Pharmacopœial tinctures and extracts may vary greatly in strength and in the active ingredients they contain. The extract of belladonna prepared in a given year has given an alkaloidal strength of from .73 per cent. to 1.17 per cent.

Of late years, therapeutists have come to see that all medicinal preparations, where practicable, should be standardised, and although the "British Pharmacopœia" is notoriously slow in adopting any improvement in pharmacology, we have already at our command a large number of standardised tinctures, constant in strength. These are made by many leading chemists in England, and a short practical use of these preparations will convince every prescriber of their superiority over preparations, the strength of which may vary according to the amount of sunlight, quality of soil, and subsequent manipulation under which the plant passes, before it emerges as an official tincture or extract.

Constant tinctures were brought before the notice of the profession four years ago by Squire, of London; they were very favourably reviewed by the leading journals (*Lancet*, March 7th, 1885, *British Medical Journal*, February 14th, 1885), but their use has not yet become so general as prudence and caution would direct.

I am, yours faithfully,

Kirkby-Stephen. BENJAMIN WALKER, M.D.

ARSENIC EATING.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

SIR,—It is not a case of doubt: I am utterly incredulous in regard to arsenical toleration, and shall remain so until a person shall be shewn to, say, the Medico-Chirurgical Society, who is taking half an ounce—only two grains of arsenious acid—daily, without inconvenience.

Maclagan's story is identical with the original of von Tchudi's, and presents the same elements of inaccuracy. Neither tell us what tests were used for the identification of the "arsenic," nor the precautions taken for ascertaining that the men really swallowed it, and that arsenic had not been added to the urine after micturition. And, as it is not usual for travellers in Syria (Styria?) to encumber themselves with chemical apparatus and tests, how did Sir Douglas's son improvise the former and find the latter? And, above all, what were his qualifications as a scientific observer?

The action of opium is purely physiological, therefore, it may be tolerated to any extent; arsenic acts medicinally only in the minutest doses, beyond these it is chemically a disintegrant, an irritant, an escharotic; we might as well attempt the toleration of concentrated nitric acid.—Very obediently yours,

G. CADOGAN-MASTERMAN.

To the Editor of THE PROVINCIAL MEDICAL JOURNAL.

A CORRESPONDENT would like answers to the following queries:

BULLOCKS' BLOOD.—Will any competent reader give information of the value of this agent; how to make defibrinated bullocks' blood in scales, and how long it will keep good in stoppered bottles?

ACID GLYCERINE PEPSINE SOLUTION.—What is the most efficient method of making this useful preparation?

STABLE SOLUTION OF PODOPHYLLIN.—The pharmacopœial tincture being an inelegant preparation, how may a constant solution or tincture be made which will be clearly miscible with infusions, acids (weak) or alkalies?

INFANTS' FOODS.—Where can we obtain a reliable tabulated analysis of the many tinned foods for invalids and infants?

PANCREAS SOLUTION.—Can any reader give a good working method for making pancreas solution, and a method for pancreatising tinned foods?

VOL. VIII.] DECEMBER 2, 1889. [No. 96.

Our Portrait Gallery.

HENRY WILLIAM FREEMAN,

F.R.C.S.I., L.R.C.P. LOND.

H. W. FREEMAN was born in 1842 in the neighbourhood of Westward Ho! North Devon, rendered famous by the writings of the late Charles Kingsley. He was educated at the Bideford Grammar School, and subsequently by private tuition, and at an early age he passed through the usual pupilage with a well-known local practitioner of medicine. As an earnest student he became well known to, and respected by his teachers during his curriculum at the Middlesex Hospital, and we find him year by year first prizeman in most of the academical subjects. He was Governor's prizeman in surgery, medicine, and general excellence in 1863; and by the unanimous recommendation of the medical staff he succeeded in obtaining the following year the post of Resident Medical Officer at the Royal United Hospital, Bath. In the year 1881 he was appointed one of the Senior Surgeons of that institution.

A busy, active life came to Mr. Freeman early in his professional career, and it is pretty well known how well he made use of his opportunities. In the Jubilee year he offered as a free gift to the city of Bath a valuable property outside the city as a convalescent home, subject to its being annexed to the Royal United Hospital, of which he formed one of the senior staff; but his offer fell through, notwithstanding his determined efforts, owing to the endowment fund subscribed being inadequate for future maintenance, and all his intimate friends well knew at the time how deep was the grief, and bitter the disappointment, when his projected scheme was abandoned.

For several years he has followed persistently the custom of visiting all the leading spas and health resorts in France and Germany; and during the International Medical Congress in America in 1887 he made himself acquainted with the springs of Saratoga, and those of Virginia, the main object of these travels being to satisfy himself what position Bath and its mineral waters should rightly hold in the system of modern balneo-therapeutics. Mr. Freeman soundly believes in the undeveloped virtues in drinking the Bath mineral waters, and maintains, for example, that the Bath mineral, lime-sulphated water when drunk "COLD" for renal and bladder disorders is an analogue of the Pavillon water of Contrexèville, and he is busy in classifying his results. He is indefatigable in presenting to the Bath Corporation the necessity of raising new buildings in connection with the baths, for new treatment, and for hygienic and social purposes, and he is a consistent believer in the baths of Bath when estimated by their thermality, their extended modes of administration, and their varieties of application.

As Mayor of Bath he entertained on June 13th, 1889, H.R.H. The Duchess of Albany, the *élite* of the county and surrounding neighbourhood, and a very large and representative body of the medical profession from all parts of the United Kingdom, at the inaugural ceremonial opening of the new massage baths; and it is conceded that the function was a considerable success, and one that will be remembered as a red letter day in the annals of the "City of the Warm Vale." We published a full account of this interesting ceremonial in the July issue of the "PROVINCIAL MEDICAL JOURNAL," and we can only repeat our estimate of it, that it was in every way a successful ceremonial, and a credit to its Mayor.

Mr. Freeman is the author of the new work on "The Thermal Baths of Bath, with the Aix Massage, and Natural Vapour Treatment," and his best surgical papers are those on "Hysterectomy;" on "Recurrent Fibromata of the Neck in Relation to the Branchial Arches;" on "Extirpation of the Rectum;" on "Cavernous Angioma of the Tongue," etc. He is a deep believer in self-reliance and incessant labour, and is looked upon as a cultured speaker, possessing the courage of his opinions, expressing himself fearlessly and concisely, and giving his hearers the impression that "what his heart thinks, his tongue speaks."

Original Communications.

NOTES ON THE TREATMENT OF ACNE.

By H. Valentine Knaggs, M.R.C.S., L.R.C.P.

Among the numerous skin affections of modern days with which we have to deal, one of the most troublesome is acne. It is a cause of extreme annoyance to the sufferer, and attacks a portion of the body—viz., the face, which cannot by any manner of possibility be screened from observation. Hence the patient is only too ready to adopt any reasonable means to bring about its cure. Although the diagnosis is simple and easily made, the disease itself is too often found to prove rebellious to the action of drugs; and in order to effectually lay down any definite and successful mode of treatment, it becomes an important point to study the pathological characteristics of the affection.

Acne is generally considered to be an inflammation of the hair follicles, in which the sebaceous glands are stimulated to secrete their peculiar oily caseous matter to such an extent as to produce distension of the ducts. As a result, disfigurement and a papular or pustular eruption ensues. The disorder occurs for the most part at puberty or during early manhood, when vitality is at its highest pitch, and when the procreative functions are for the first time started into active operation.

Most modern authorities insist strongly on the relation between acne and sexual hyperæmia. The further this question is studied, the more will the force of this connection be felt. The various vital functions of the nervous system are mainly carried on through the agency of complex nitrogenised and phosphorised fats, such as lecithin, cerebrin, neurin, and similar bodies. When the compounds are secreted in considerable excess, as would be the case when the sexual functions are in a state of great activity, it becomes an interesting problem as to what becomes of their by-products. One might reasonably surmise that the system, having more fatty matter than it knows how to dispose of, allows a certain portion of the waste to filter through the sebaceous glands; in other words, instead of the hydrocarbon products of lecithin, cerebrin, and possibly also ingested fat derived from food, being burnt up or deposited in the tissues in the ordinary course of events, they are retained in the blood, and leak out through the hair follicles, so causing acne.

On the other hand, it is generally noticed that highly delicate or consumptive people are remarkable for the clearness of their complexions, and for the decided absence of fatty secretion connected with the hair follicles, while their sexual functions are usually in abeyance. I think one may not unreasonably conclude, then, that the relation between acne and the sexual organs is certainly more than a passing one. Moreover, Professor Brown-Sequard in his recent experiments appears to consider the semen as a vitalising agent, while it has been proved that the hypodermic injection of seminal fluid had a most remarkable rejuvenating effect both on himself and others. We may all have our doubts as to the desirability or utility of these injections in the case of persons who have passed their allotted sphere of life, although the importance of verifying the statement that the secretion of semen has an important influence on the economy is material.

Now, consumptive patients of the kind mentioned are usually much benefited by the administration of cod-liver oil, by the use of alkalies, which may serve the purposes of promoting the absorption of fats by the intestinal fluids, and by the hypophosphites. Fats and oils administered internally, although not generally classed as such, have, I believe, a marked aphrodisiac effect. The natives of India have been known to use frictions of oil to the surface of the body under the supposition that the secretion of semen would thereby be augmented. Perhaps it is that cod-liver oil, given to a young consumptive adult, supplies vitalising elements to the economy, which, through the deficiency of complex nitrogenised and phosphorised fats, are much wanted. Probably, also, a reason why the hypophosphites do good in similar cases is that they supply a form of loosely combined phosphorus, which takes the place of lecithin, a body that is found in some quantity in the seminal fluid. Lecithin is a glycerin-phosphate of neurin, or a combination of glycerin-phosphoric acid with neurin; hence there must be a close chemical resemblance between this so-called fat and the hypophosphites.

If we regard acne, then, as merely a leaking of superabundant fat through the oil glands of the skin, the treatment based upon that hypothesis becomes easy, and, according to my experience, decidedly efficacious. The kind of remedies upon which I place most reliance are either substances containing, or rich in, oxygen, or volatile stimulant hydrocarbons of the alcohol series.

In order to reduce the sexual hyperæmia, with its attendant excessive vital energy, we must direct the patient to take plenty of vigorous exercise. In the case of a youth or young adult, he should be urged to join a gymnasium, or to regularly practise such arts as swimming, boating, lawn tennis, cricket, dancing, and the like, during his spare time. Then he should take every morning a cold bath; this gives tone to the system generally, and to the skin in particular, while it subtracts a considerable amount of animal heat which must be made good by the combustion of an extra quantity of fatty and hydrocarbon foods. As to diet, unless vigorous exercise is indulged in, the patient should be enjoined to eat animal food but sparingly, and to especially avoid cooked or decomposed fats, such as the fat or dripping of butchers' meat, pastry, etc.; while, should constipation be present, whole meal bread and wheat meal porridge are useful. By a judicious dietary we can, so to speak, cut off supplies by interdicting sundry articles of food which, in an ordinary way, would serve to increase sexual hyperæmia, and equally promote an increased secretion by the sebaceous glands. At the same time, by careful hygiene and exercise, the system is enabled to work off, or rather burn up, any excess of fatty matter. I believe the cold bath should hold foremost rank as a means of getting rid of this troublesome skin disorder. At times the Turkish bath may effect improvement by clearing the blocked ducts of their comedones, but the benefit that patients derive from this hot-air bath is often not lasting, and they are very prone to relapse.

With respect to therapeutic measures, a most valuable remedy is oxygen. No doubt, in the form of inhalation, it should give the best results, but this is out of the reach of most of us, and therefore it will be necessary to fall back on fitting substitutes. To drink oxygen water, as supplied by Brin's Oxygen Company, is a good way of administering the gas. It should be taken to the extent of from one to two syphons per diem. Since much of the gas is lost in pouring it out, the patient should apply his mouth to the nozzle, then press the tap, and so drink it when the fullest possible

amount of the gas will be had. Then we can administer peroxide of hydrogen, preferably in the form of ozonic ether, in doses of fifteen minims to a drachm, three times a day in water. This volatile liquid promotes glandular secretion, and when given in cases of diabetes is found to oxidise sugar. In acne it is highly probable that it oxidises fat. One might add, by the way, that ether alone markedly increases the digestibility of cod-liver oil and other oils, when administered in combination with them. The compound of ether and peroxide of hydrogen is certainly a good one, and is decidedly efficacious in cases of acne. Lastly, we have chlorate of potash, which observers declare passes unchanged through the body. It has been supposed to give oxygen to the system; whether that be the case or not, it will be found to act satisfactorily in acne, more especially when combined with tinct. guaiaci, or tinct. guaiaci ammon. This mixture is, however, somewhat nauseous, and I would suggest a lozenge containing five grains of chlorate of potash and two and a half grains of guaiacum resin in each, as a more elegant way of administering the same.

Guaiacum, a remedy which I have found exceedingly useful in cases of boils, although in this respect it is not quite so curative as sulphide of calcium, yields very good results in some cases of acne. From its composition, the resin may be classed as a hydrocarbon, and like ether, alcohol, and other volatile bodies of an allied nature, when given in small doses acts as a stimulant, quickening the circulation, and so promotlng increased combustion of heat-producing food. Guaiacum is best administered in the form of lozenges, containing four grains in each; from three to six, or even more, being given daily. The drug further sets up a mild irritant effect on the intestine, and thus acts as an efficient laxative.

I think it must be conceded that acne is more frequently seen in young adults who are rigid abstainers, than in those who are moderate drinkers of alcohol; therefore, as experience will demonstrate, a judicious resort to beer or light wines may assist in removing the disorder. These beverages act in a similar manner to ether or guaiacum in accelerating the circulation and promoting increased combustion of the hydrocarbon foods.

According to my experience, but little reliance can be placed in local applications. Some form of sulphur is the medicament usually employed, and in the main, perhaps, this mineral is one of our best topical remedies. Still, if practitioners would devote more attention to general measures, to the exclusion of mere palliatives, I think they would find, as I have roughly endeavoured to set forth, that oxygen or volatile stimulant hydrocarbons exert a permanent and lasting effect in these cases, particularly if combined with a careful dietary and a regular and judicious use of the cold bath.

THE MEDICAL TRAINING OF THE COUNTRY PRACTITIONER OF THIRTY YEARS AGO.[1]

By A. Hirst, M.D., F.R.C.P. Ed.

The subject I bring before your notice this afternoon has suddenly become one of the questions, if not the question of the hour, in our profession. The address of Dr. Wheelhouse, our president, at the annual meeting at Leeds, lately held, has evoked rather a sharp controversy on the subject, and has brought out a variety of opinions with regard to it. Having commenced my professional career by the old-fashioned apprenticeship system, I pin my faith upon it. Dr. Gairdner told us in his address that he believed in thoroughness; I believe that every gentleman in this room does the same, but I think few of us will agree with him in thinking that to spend four years in studying a few cases thoroughly will fit a man to undertake in an efficient manner the whole duties of a good general practice. What thoroughness I have about me I learnt during my apprenticeship. I commenced by dispensing the medicine, under the supervision of the senior pupil, making pills by the thousand, mixing and wrapping up stocks of powders, rubbing up ointments, spreading plasters, etc. Constantly consulting a good work on materia medica, and also one on practical chemistry, I soon got a good practical knowledge of drugs and their combinations, having some one near at hand frequently during the day ready to solve any doubt, and supervise all I did. I have seen no system adopted in any school of medicine with regard to that kind of work from which I could have derived anything like the same amount of benefit. In the meanwhile, as a variation, we had a fairly good work on anatomy, one on physiology, and a drawer full of bones, which we worked up for a change alternately with the other work, daily trying to add a little to our general stock of knowledge. Shortly a drive was taken with the principal in his gig on his rounds, who on the way discoursed on medical matters in general—methods, duties, obligations, requisite thoroughness, and disasters likely to result from a single mistake. Patients who saw one with him were aware that one was a pupil, and gradually began to notice one, which paved the way for something further. By and by he takes one to see a case near at hand, commencing with one of a typical character, which of course leads on to others—reading up in connection with each case. Meanwhile, one is reading up Swayne's "Obstetrics," the anatomy of the pelvis, etc., awaiting the first midwifery demonstration. One received solemn warnings from the principal as to the necessity for thoroughness in that especial branch.

A case of midwifery occurs near at hand; the patient having no objection, one is taken in to stand quietly by, observe closely, and ask questions afterwards. One saw for the first time the tying of the umbilical cord, the removal of the placenta, the application of the binder, and heard the general instructions which were given. The same course is repeated a few times. Then just afterwards someone sends in a hurry. The principal is out. After a short wait one presents one's self, saying that the principal has been sent for, and in the meantime but wait his arrival. The pains increase. One is sorry that the chief is not present, and expresses sympathy, and as a last resource help is offered. There being no time to say nay, one places one's hand gently on the perineum: the child is born in a few minutes; one immediately ties and separates the cord, and when another pain occurs, traces the cord to its attachment to the placenta, and feeling the mass in the vagina gently removes it. Thanks for great and skilled assistance are profusely rendered, and one's praises are sounded abroad. Afterwards one is then quietly initiated in the uses of ergot, opiates, hæmastatics, the forceps, etc., and, chief of all, the virtue of patience, the tonic effect of cheerfulness, and the inadvisability of being too meddlesome.

[1] An address prepared for the meeting of Lancashire and Cheshire Branch of the British Medical Association, held at Blackburn, November 6th, 1889.

In the meantime, cases of measles, scarlet fever, whooping-cough, varicella and variola cropped up, which one had an opportunity of visiting, and learnt to discriminate between them, reading up each subject as opportunity presented; comparing and digesting, as far as possible, the facts connected therewith. When we came to diseases of the internal organs, I felt a knowledge of anatomy and physiology to be necessary. A little practical knowledge was available on the quiet. Organs, such as eyes, hearts, and lungs of animals were attainable, and made use of.

I cannot think that the preliminary training which I have so imperfectly described is to be utterly despised. I have never repented having undergone it. After such a training, good lectures are thoroughly appreciated, and hospital practice can be cultivated with an educated eye and hand, and give the necessary finish requisite for a diploma. But so far as my experience goes the clinical teaching of a hospital as compared with that under the supervision of a good general practitioner as a preparation for general practice is not to be compared. In one case the student is one of a crowd; in the other he is the pupil.

After such a preliminary training, even if a few old-fashioned notions have been picked up, the three years hospital practice will be likely to dispel them. But the general practitioners of the present generation are not so far behindhand as some people imagine. One rather smiles when one hears some speak in tones of derision of the country practitioner. He is trained to rely upon himself. He must be thoroughly acquainted with his duties, as help is very frequently not to be had in emergencies. He feels his responsibility, and acts accordingly.

Cash being rather scarce at the end of my apprenticeship, I went up to London and acted for some time as an unqualified assistant. I was astonished to find the great difference that existed between the knowledge and the self-confidence of the country practitioner compared with the Londoner in general practice. Cases that I had been accustomed to see undertaken without the slightest hesitation in the country, were sent to the hospital, or a consultant was called in to see them. The fellows of old standing seemed rather amazed when the much despised unqualified assistant in an intricate case of midwifery could quickly turn and deliver a child, or when they had torn the head by force from the body, or rather the body from the head, he could quickly bring it, as he did upon two occasions, safely—in one having to break down the skull in order to remove it. Many other cases I might enumerate.

The plan I have so inadequately sketched, added to two and a half years attendance upon lectures and hospital practice, was the general system carried out thirty to forty years since, and I maintain that on the whole the results were not to be despised. Great advances have of late years been made, to which country practitioners have contributed their share. To keep up with the times a thoroughly searching, preliminary, scientific examination should be passed before the commencement of medical study, then a two years' apprenticeship with a practitioner who knows his duties, has opportunities for practice on a fair scale, and is willing to impart knowledge. After the apprenticeship, three years of close attention to hospital practice, and chemical, physiological, hystological, and other collateral branches of the medical and surgical science and art, will, I think, form a fairly good basis to found a practice upon.

NEWBOULDIA LÆVIS IN THE TREATMENT OF DYSENTERY.

By J. Farrell Easmon, M.D., etc.

Many of the medicines most highly prized to-day, such as cinchona, coca, jaborandi, ipecacuanha, araroba, etc., were at one time empirical remedies employed by uncivilised peoples. There are doubtless still, among the remedies employed by the natives of Africa, many powerful drugs that may hereafter prove of value to the human race, when their properties have been investigated in a thoroughly scientific manner by eminent therapeutists, physiologists, and chemists. Being situated in a country whose *materia medica* is almost unknown to Europeans, and having excellent opportunities of obtaining the plants in general use here as medicines, I have commenced a series of experiments with the more promising of the native remedies that have come under my notice, and hope to communicate from time to time the results, whenever I obtain evidence that any of these remedies are deserving of more scientific investigation than is possible with the means at my command in this colony.

The drug to which on the present occasion I desire to direct the attention of the medical profession, is one which is hitherto entirely unknown out of Africa as possessing medicinal properties, and belongs to a family of plants concerning the medicinal qualities of which but little has hitherto been recorded.

Botanical Characters.—As generally met with on the West Coast of Africa, the plant is a straggling tree, from seven to fifteen feet in height, bare below, but leafy at the summit of the trunk and branches. Under favourable circumstances it grows to the height of seventy feet. The natives employ it in making fences around their compounds, and especially around their fetish grounds; the only reason for this selection that I have been able to discover being the hardiness of the plant, which readily grows when so employed. The plant belongs to the natural order, *Bignoniaceæ*, an order which has not as yet received the attention which it deserves from pharmacologists. In the "National Dispensatory" of Stillé and Maisch, and in Johnson's "Medical Botany of North America," the medicinal properties of *Bignonia Catalpa* and *B. capreolata* are briefly referred to; and in the *Pharmaceutical Journal*, September 1, 1888, p. 162, reference is made to the therapeutical uses of the *Tabebuia longipes*, or white cedar of British Guiana, a plant of the same natural order. Moloney refers to a species of Newbouldia called *Kindee* or *Brochee* in Sierra Leone, used by the natives of that place in fevers; to *Spathodea campanulata*, used in the treatment of ulcers in Gaboon; and to *Kigelia pinnata*, used by the natives of the Gold Coast in rheumatism and dysentery.

My first experience of the drug was while a youngster at Sierra Leone, where it was first administered to me for the acute malarial splenitis, so common among children in that unhealthy peninsula. A decoction of the bark of the trunk and roots was given internally, and over the enlarged and painful spleen a poultice consisting of the bruised leaves, with native spice (*Habzelia aethiopica*), was put on quite hot. The relief was always certain. In 1879 and 1880, when in practice at Sierra Leone, I used the drug with success in all acute malarial enlargements of the spleen. It was about this time I obtained my knowledge of the influence of the drug on the uterus. I found out accidentally that the decoction was largely used in the treatment of the puerperal state by the Susus and Timanis (native

tribes around Sierra Leone), among whom it was the sovereign remedy in *post-partum* hæmorrhage. Uufortunately, it was often combined with the native spice already referred to, so that although good results were obtained in many cases, it occasionally failed in others. This I soon discovered was due to the effect of the spice.

The contractile power upon the spleen and uterus displayed by the drug led me, while in the Quittah district in 1881 and 1882, to its trial in the treatment of dysentery due to an atonic condition of the large intestines, and my results were so satisfactory that I was led to employ it in all cases of dysentery that came under my care in my dispensary practice in that district. My subsequent experience in the wards of the General Hospitals at Accra and Lagos, of the utility of the drug in all cases of dysentery, induced me to forward specimens of it to Professor Sydney Ringer, of University College Hospital, London, in 1883, with a view to its further investigation. These were handed by him to his colleague Mr. Gerrard for chemical examination, but as he found no alkaloid, he was discouraged and did not continue his researches. I have since used the drug in my private and public practice, and it has been employed also by some of my colleagues in the treatment of dysentery, as met with on this coast, with complete success.

In short, in all conditions indicative of atony of the involuntary muscular fibre newbouldia is useful.[1] In all passive hæmorrhages it appears to be useful when given in full doses. It seems to act in moderate doses upon the involuntary muscular fibres generally as a tonic and alterative, and in large doses as a direct stimulant. What the precise nature of its action in dysentery is, I cannot say. Certainly it is not simply as an astringent. Possibly it is by modifying the circulation in the intestines by its action on the muscular coat of the arteries, and of the intestines, and probably of the spleen also, thus producing tonic and alterative effects upon the diseased mucous membrane. And here I would draw attention to the following pregnant remarks of Sir Thomas Watson: "The very frequent coincidence or alteration—in some places—of dysentery with intermittent fever has given rise to the opinion that both these diseases are alike attributable to the malarious poison. But dysentery prevails where there is no other evidence of the presence of malaria. You may recollect that when we were upon the subject of ague, I showed you that its repeated paroxysms were attended with extreme and increasing congestion of blood in the internal organs, of which congestion, the tumid spleen, the so-called "ague-cake," was an effect and a token. Now whatever gorges the splenic vein, gorges its tributary, the inferior mesenteric, which carries the blood from the rectum and the descending colon. Upon such congestion of the mucous membrane, inflammation is readily engrafted, and in this indirect way dysentery may be said to result from the marsh effluvia. Ague is an effect of malaria; and dysentery is sometimes a sequela of ague. In precisely the same manner dysentery is apt to supervene—in hot climates especially—upon hepatic congestion and disease."—["Practice of Medicine," fourth edit., vol. ii., pp. 541, 542.]

Preparations.—The preparations used by me have been (*a*) *decoction* of the fresh bark of the trunk and roots; (*b*) *fluid extract*, prepared by maceration and percolation, of the strength of one of bark to five of rectified spirit. Dose of the *decoction*, one to two ounces; and of the *fluid extract*, fifteen to sixty minims. In the first stage of dysentery the treatment is preceded by a full dose of castor oil in ordinary cases, or a saline purgative when there is more blood than mucus in the stools. As soon after as the bowels have acted twice or thrice, I give full doses of the drug, and repeat these until the bowels are constipated; the administration is then continued at less frequent intervals until there have been no stools for at least twenty-four hours. Then according to the circumstances, the drug is either continued in smaller doses for a few days, or discontinued altogether. A final aperient may be necessary to complete the cure.

Occasionally newbouldia, especially when given in full doses, produces *griping*; this I overcome by giving it with the *tinct. chlorof. co.* and occasionally with some preparation of *Morphia* (which I prefer to opium in cases of dysentery).

It is hardly necessary to add that in all cases of dysentery no matter what the nature of the medicinal agents employed, *dietetic treatment is essential* in the successful management of cases.

In administering to females, it should be borne in mind that this drug stimulates the uterus and may therefore, as I have known it do, cause a premature appearance of the menses, or produce abortion.

I trust that the above remarks will be sufficient to indicate, to a certain extent, the line of usefulness which may be followed out in further experiments in the continents of Europe or America with this interesting drug.

[1] I hope to publish in due course my observations, from clinical experience, on the pathogeny of dysentery on this coast.

ALBUMINURIA IN ITS RELATIONS TO LIFE ASSURANCE.[1]

By A. Rabagliati, M.A., M.D.,

Medical Adviser to the Friends' Provident Institution.

A group of cases which have recently come under my observation leads me to make some remarks on this subject. As we shall see, there is no agreement among medical advisers to insurance companies on this most important question, and there is, in consequence, no uniformity of behaviour among the offices in their dealing with the public in regard to it. I must confess at the outset to taking a somewhat grave view of albuminuria in its bearing on the expectation of life; but there is a firm basis of facts on which opinion as to the value of such lives may be founded, and I think that by paying attention to these facts greater certainty as to the true value of the lives affected may be reached, and greater uniformity of practice, therefore, may be attained. Of course each case must be decided on its own merits in respect of personal history, the general impression the life makes on the medical examiner, and the constitutional or family history of the applicant. As to the general impression conveyed to the medical examiner, and by him transmitted to the insurance company, as that is wholly a matter of skill, experience and intuition, I do not propose to take up time in discussing what each examiner and each office must gauge for himself and itself. Here, if anywhere, genius comes in, and an examiner will be right or wrong according to the amount of his experience and the intuitional power he is possessed of, while the office will follow his advice implicitly, or make some modification in the

[1] Read at the British Medical Association Meeting in Leeds, August, 1889.

course suggested, according to the amount of confidence they place in him.

In order to get at once to the heart of the business I will relate a case which occurred to me in the beginning of 1888, merely premising that, after the curious sequence prevailing in organic affairs (in accordance with which one experiences a run of cases of a certain kind in a short time, which cases may be wholly absent, or occur only rarely during many years immediately succeeding) this case proved to be the first of a succession of about eight cases presenting very similar features. A man, aged about forty, presented himself for examination. He was about five feet ten inches high, weighing about thirteen stones, well built, vigorous looking—perhaps a shade too stout—measuring about thirty-eight inches round the waist, and about the same round the chest, with full, easy, and regular respiration, and nothing abnormal about the lungs. The apex beat in the fifth interspace below and not outside the nipple; no reduplication of first sound or accentuation of second; pulse steady, soft, and regular, seventy. Personal history good; had never had any but slight illnesses. He was not a teetotaller, but described himself as strictly temperate—had, for instance, never been drunk in his life—although giving one the impression of being what is called a free liver, and perhaps taking rather more alcohol than was physiologically good for him. To come to particulars, he took say two pints of beer or a pint of champagne, with perhaps a couple of glasses of sherry during the day, and two glasses of whisky and water at night. There were no nervous symptoms, no tremulousness of hands, no defect of vision or other special sense (did not use glasses). Bowels regular, tongue clean, no hepatic engorgement, no piles, appetite good. Had no urinary troubles; did not get up at night to make water. The water is muddy, he says, from time to time; but whenever he has consulted his doctor about this he has been told there was no organic disease, only indigestion. I was just commencing to congratulate myself on having an average life to deal with, and had just said to him that I thought he ought to pass, when, on asking him for a sample, I found the urine acid, 1024; no sugar, but containing a trace of albumen. On microscopic examination it showed abundant specimens of oxalates. I found no casts in that specimen. On making this unpleasant discovery repeated specimens were asked for and carefully examined. On one of these occasions the following was the state of things: Three specimens were taken. No. 1 was passed before bedtime. Some fleecy sediment appeared in all the specimens (some 7 per cent.) on standing for some hours. To the microscope it contained oxalate of lime and a few leucocytes; 1024; acid; albuminous. No. 2 was passed on rising in the morning. It had the same characters, but one or two faint hyaline casts were also found. In No. 3, which was passed after lunch, the characters were the same, but the oxalate of lime crystals were small, the leucocytes more numerous. There were a few faint hyaline casts and one or two granular ones, and there was also a fungoid growth mostly in a four-celled moniliform shape. This gentleman was seen by the London examiner of the company to which he proposed, and took in addition the opinion of a distinguished London physician, who both found albumen and oxalates, but failed to find casts.

Very strangely, within a month I had had three more cases exactly similar, in which the same combination of a faint trace of albumen with oxalates was present. No casts were found. All were, I ought to say, rather free in their use of alcohol. But I had also another case, almost exactly similar, in which the man took exceedingly little alcohol—not more than a glass of light ale at dinner time—and often none at all. In this last case I was confident, however, that a small oxalic stone formed in the right kidney, and when this got away the man recovered and remains well. I may add, that some years ago, he had an exactly similar attack, from which also he recovered. But except this one, all my cases of albuminuria with oxalates were in men who ate and drank freely, and whose habits, therefore, in both these respects tended to the production of gouty or lithæmic nephritis. In each of the four first named cases the offices concerned rejected the lives, but allowed a further examination, if desired, after the lapse of twelve months (in some instances less). Now the after history of these cases was very interesting. All but one recovered; that was case one, which, on examination eighteen months after, proved to be in the same state as to the presence of albumen, oxalates, and the presence of a few casts, as it had been before. Case 2 was examined again in a short time, having in the meantime gone on a restricted diet, and also having submitted to a considerable reduction of alchohol; and, as he was albumen-free, he was accepted by an English office (not the Friends' Provident I may say, and I may add I am not dealing in this paper mainly with the experience of that office) at the ordinary rates. His age was twenty-eight years. Case 3 (also aged twenty-eight years) got quite well under similar treatment, along with the free use of a mineral water found near Vichy *(Source anonyme)*, and was to come up again for examination for an English life office, but has not yet done so.

Judging from my experience of the behaviour of that office, I have little doubt they would have accepted the life on the disappearance of the albumen, had he come up as they wished. Case 4 was aged forty years. No doubt this man, as a rule, takes too much alcohol; but he got a fright when albumen was found, reformed his ways, abstaining wholly from alcohol, and much diminishing, at my instigation, his nitrogenous food; and in a couple of months his urine was albumen-free, and normal in all respects. He re-applied to the office (an American one), was reported sound; the London office of the Company issued a temporary policy, but when the the American Board sat on the case, they would not look at it, and unconditionally rejected the application. This shows a great difference of practice in offices. But the after history of this case is instructive. Whether under the influence of the disappointment of being rejected or not, I cannot say, but applicant has since then returned to his old habits, and both the albumen and the oxalates have returned. For him, at least, the only chance of life, and any degree of health, is total abstinence from alcohol, and the use of flesh sparingly. As these conditions are difficult of attainment, and as an office hardly could issue a policy, conditionally on their being maintained, it seems as if that office had acted wisely in rejecting the application.

The fifth case I have mentioned did not apply for life insurance, but if he had done, I think I should have recommended him probably at a small advance. I know him to be systematically abstemious, both in eating and drinking, and believe that (accidents excepted) he will probably attain the average duration of life. Now I come to two other cases of albuminuria—cases 6 and 7.

These differed from the previous ones in this, that there

were no oxalates stated to be present: in one, no statement was made (the age thirty years) as to oxalates; sp. gr., 1020; acid; no sugar; trace of albumen; London physician recommended six to seven years advance, and I agreeing, the office granted the application. In case 7, the applicant was forty-eight years old, a stout man, whose urine was on three different occasions acid; 1029, 1027, and 1025 sp. gr.; each time loaded with lithates, and each time showing a trace of albumen. No statement was made about casts. The examiner said he attributed little importance to the conditions, and recommended either no advance or a small one. On considering this case, it seemed to me that the high sp. gr., the lithates, and the albumen together, constituted a dangerous combination, in fact, that they suggested lithæmic nephritis; and I felt compelled (notwithstanding that no statement was made that there was either reduplication of the first sound of the heart, or accentuation of the second) to recommend a considerable advance of seven to ten years. I do not know that there is any advantage in multiplying cases; but I should like just to refer to an eighth, where the applicant was fifty-three years of age, and whose urine was 1012, acid, without sugar, but showed, in the first sample, taken in the forenoon, 5 per cent. of albumen. A morning sample showed a trace; an evening sample was albumen-free. Postponed for three months. On re-examination at the end of that time, the facts were: 1008, acid, no sugar, and trace of albumen. The medical examiner attributed little or no importance to the condition, and recommended acceptance of the risk at a slight increase. I could not take so favourable a view, and recommended a heavy advance, saying, that the most I could recommend was an endowment policy payable at sixty-five years, and that on that I would recommend a 20 per cent. advance.

Now the question is—can we suggest any principles on which these cases should be settled? And are there any facts whose consideration may lead to more definite and precise dealing with them? It is of comparatively small moment to quote authority. Dr. George Johnson, in a paper appearing last February, and written in part to refute an erroneous statement made regarding his views on albuminuria, says, that "the presence of albumen in the urine, though small in amount and occasionally intermittent, is always pathological." And again, "No prudent medical officer would advise that a proposed assurer with a trace of albumen in the urine should be accepted at the ordinary rate of premiun."

Dr. Saundby, on the other hand, lays stress on the fact that albuminuria may persist for years without disease of the kidneys being set up. In one case he quotes, he says, "that the albuminuria has lasted for twenty-one years without the supervention of renal disease." Our knowledge of facts of this sort (if facts they be) is recent. Dr. Grainger Stewart found albumen in about one-third of 505 persons who were presumably healthy; but among these, sixty-two out of 100 persons, about or over sixty years of age, had it; among 100 children it was found in only seventeen. But the question remains: Would it have been safe to insure Dr. Saundby's case at ordinary rates twenty-one years ago, or would it be safe now? And would it be prudent to accept Dr. Grainger Stewart's sexagenarian albuminurics at ordinary rates, or does his inquiry not rather prove that more persons have crippled renal organs than is commonly supposed? I confess that is my reading of the evidence. Dr. Lauder Brunton says, "it would be as grave an error to assume that every individual who has albumen in the urine is suffering from serious disease, as if we were to suppose that every patient whose urine contained sugar was necessarily suffering from diabetes." But there is surely a great difference between sugar and albumen in this, that the latter ought not to be found in urine at all; while the former is always present to some extent (at least, I have always found it, since learning to treat for it quantitatively, when I have looked carefully enough for it). Dr. Parkes found temporary albuminuria in 12 per cent. of his hospital cases. Again, it was found by a New York life insurance company that 9 per cent. of all persons applying for life insurance showed signs of albuminuria. It seems to me that the American insurance offices are disposed to think more gravely of the presence of albuminuria than some, at least, of the English ones; at least, if I may judge from my experience, and from the fact that Dr. Stillman, in his "Life Insurance Examiner," says, that "the continued presence of albumen in the urine is sufficient cause for rejection *without the co-existence of any other symptoms*." How different is this view from that of many of our authorities in England, and how different must be the practice of offices advised by men holding views so opposite!

When, say a trace of albumen, is found in the urine of an applicant for insurance, the following course should, I think be taken. First of all I take it the presumption is against the life. A man with albuminuria is not so good a life as one without it. Even those will I think admit this who contend that the presence of albumen is not *necessarily* a serious sign; even they would prefer not to have found it. The next point is to determine the sp. gr. Is the sp. gr. above 1020? Then we have a *suggestion* of lithœmic nephritis, either present or in prospect, for we know that the continued passage through the kidneys of urine, loaded with excess of nitrogenous waste, is of itself a common cause of gouty kidney. Is, on the other hand, the sp. gr. below 1010? Then we have a *suggestion* of a more advanced state of degeneration in the kidney, especially if we find that the low sp. gr. is a constant and not a temporary phenomenon. In either case we must examine for casts, and we ought to get several specimens of urine for this purpose. As pointed out by Dr. Saundby, that passed between breakfast and early dinner is the most favourable for finding them. Of course failure to find casts is not a proof of their non-existence. Ability to find them depends very much on the power of the observer. I may observe that staining the slide with methyl blue is a great aid in this direction, so great in fact, that if they do not appear after this process I incline to think they may be confidently pronounced absent. I suppose if casts are present we ought to counsel rejection, or at least a very heavy advance if the life be young, and absolute rejection if over 45-8. But if casts co-exist with constant sp. gr. of 1010 or less, reject absolutely. Along with these facts must be considered the state of the heart. A low sp. gr., with trace of albumen, casts, and reduplication of the first sound of the heart, with accentuation of the second sound, would compel any examiner to advise absolute rejection at any age.

Again, if we have sp. gr. over 1020, and suspect commencing lithæmic nephitis, we ought to look for other signs of gout or goutiness, as pruritus ani, gouty eczema, intermittent heart's action, or other marks. I have known two or three cases now where intermittent heart was the

only mark of gout, and where the condition was cured by the patient ceasing to eat meat. The gout that is often enough present in teetotallers is frequently, I am persuaded, due to the over-ingestion of nitrogenous food, although excess of food of any kind is apt to induce it, especially if associated as it often is with want of exercise.

Another most important point of course to consider is—what amount of alcohol is applicant in the habit of taking? Free stimulation is, no doubt, a potent cause of gouty kidney, or of the nephritis that from time to time attacks persons who are not yet affected permanently with any form of renal lesion; and if our applicant indulges in a free use of alcohol, and has a trace of albumen besides, we are bound to think more gravely of his case than if he were an abstainer, or took only an ounce of alcohol daily. As to oxalates co-existing with albuminuria, I have no wish to spend time on the discussion of what is at present more or less of a speculative question, but will only say I have been able to cure several such cases in young persons. I incline therefore rather to the postponement than to the absolute rejection of applications for insurance from young persons suffering in this way. If at the end of say six months it is found that the condition has been removed, I think we may consider the feasibility of accepting the risk, although I think even then it should be at an advance, for the reason I mentioned before, that those who have once had prolonged albuminuria (unless indeed it was due to acute nephritis, in which case it might be perfectly recovered from without damage) are not quite such good lives as those who have never shown it. Also the case quoted above (No 4) shows that if the condition can be removed, it may also readily return; and therefore, I think we ought to be very cautious in recommending such risks for acceptance.

Lastly, there is the question, supposing we entertain the application, and think we ought to recommend acceptance at an advance, what amount of advance would be at once safe for the company and fair to the assured? It is not unreasonable to assume that persons showing such signs are more likely than those who are free from them, to die of some form of disease of the urinary system. This being granted, the question becomes narrowed considerably to one of experience. Dr. Saundby states the proportion of deaths due to urinary disorders as being something like 1.1 or 1.2 per cent. of the total deaths; but it does not seem to me that this kind of comparison is of any value, because, to begin with, something like 40 per cent. of all deaths occur among children under five years of age, and it is well-known that very few indeed of these die of urinary disorders. Further, insurance examiners have hardly anything to do with children under five years of age, *i.e.*, have next to nothing to do with that portion of the population who furnish 40 per cent. of the total mortality. The question is, what proportion of adult deaths (with which alone insurance is concerned) are due to urinary diseases, and at what ages do these deaths occur? Well, the Scottish Widows Office have published valuable information on this point, and in their report for 1881 to 1887 inclusive, they state that out of 3,246 deaths, at all ages, occurring among their assured, 255 or 7.8 per cent. were due to urinary disorders. I thought it would be interesting to discover how this compared with mortality tables among the general community, and for this purpose I took the mortality from urinary diseases among our Bradford population. As most assured are males, I took only the male deaths, and in order to make the comparison as fair as possible as regards age, I eliminated all the deaths under fifteen years of age. I should have preferred to eliminate the deaths under twenty years of age, but the returns not enabling me to do this, I was compelled to take the lower figure. This being done, I found that in the three years 1884, 1885 and 1886, there occurred 3317 deaths among males in Bradford over fifteen years, which were to be compared with an almost equal number—3246—dealt with by the Scottish Widows' Company in the years 1881-7. Of these 3317 deaths, 116, or 3.4 per cent. were from urinary disorders. It appears, therefore, that comparing the mortality among a mixed male population above fifteen years old, with the specially selected class of lives insured with the Scottish Widows' Company, less than one half (3.4 per cent.) were due to urinary disorders in Bradford of the proportion (7.8 per cent.) found among the *clientèle* of the Insurance Company. I think the general inference is irresistible, that the well-to-do insured are more liable to these diseases than are a similar number of males belonging to a mixed community. (For males and females I may observe, in Bradford, the percentage of deaths from urinary disorders was 2.8 during those years.) I think the comparative frequency of these diseases among the well-to-do ought to make us additionally careful what symptoms we allow to pass us in recommending lives for acceptance. To use an expression which has obtained some currency, and owing I imagine to the custom of the well-to-do to over-load the digestive system, and to refrain too much from the healthy influences of manual work, we may say that this evidence lends force to the view that the mortality of the "classes" from these diseases is considerably greater than that of the "masses."

Nextly, according to the experience of the Scottish Widows' Office, the average age at death of those who die from urinary disorders was 62.3 years, a pretty long age. But those dying of "disease of kidneys" and "nephritis" (who formed 4.3 out of the 7.8 per cent. due to urinary disorders) only averaged 56.8 years of age.

It will be interesting to compare these results among the *clientèle* of the Scottish Widows' Fund and those which obtain in a mixed population such as is found at Bradford, with those of an American insurance company. There has just been published a very elaborate report by the Washington Life Insurance Company, of results extending over twenty-seven years, and dealing with 2,000 deaths. Of these, 123, or 6.15 per cent., were due to "diseases of kidneys, and other diseases of urinary system" (against 7.8 in the Scottish Widows' Fund, and 3.4 per cent. in Bradford); while the average age at death was 52-64 years. Of cases dying from "Bright's disease, congestion of kidneys, disease of kidneys and nephritis," there were 103, or 5.15 per cent., among the Washington Life Co.'s *clientèle*. (This compares with 4.3 of the Scottish Widows' Fund, and seems to show that our well-to-do American brethren suffer even more than we do in England from these affections, and also that they die earlier.) Of course, too much must not be founded on these figures. It will at once be said that many sufferers from kidney disease die, not of kidney disease directly, but of cerebral hæmorrhage. While this is true, I still think some advantage is to be gained from a study of the figures, and that to some extent they may be taken as a guide. Even if kidney disease should terminate in apoplexy, as it often does, we shall be within the mark in thinking of fifty-seven years as the expectation of life

in such cases, for the Scottish Widows' Fund experience is that of cases dying of apoplexy, the average age at death is sixty-one years. There therefore seems to be a great probability that over so large a number of cases, extending over a good many years, we do get a fair indication of the expectation of life among persons suffering in this way; and I am therefore disposed to suggest that where the albuminuria is slight enough to warrant us in entertaining the idea of accepting the life at all (and, of course, where complications exist, or an aggravated condition without complications, we should reject absolutely), our rule ought to be to rate up our lives to such a point as if we expected them to terminate at fifty-six or fifty-seven years. This is, as medical men know well, a very common age for chronic disease of all kinds to terminate. No doubt this is a serious view to take of such lives, though it is not, I believe, any more so than the facts warrant. Neither is it so serious for young lives as for older ones. At twenty-eight years of age, for instance, a healthy man may be expected to make thirty-six payments—which would make him sixty-four years old at death. For the slight albuminuria of twenty-eight, the new expectation would be twenty-nine years in place of thirty-six. But a man of forty, who might in the usual course live to make twenty-seven payments, has his expectation reduced to only sixteen or seventeen, which is a very serious addition indeed, and one which comparatively few applicants for insurance would accept. At forty-five the expectation would be reduced from twenty-four payments to eleven, which sounds very much like absolute rejection; and my opinion, I must say, is that at this age absolute rejection ought to be the rule. Of course, I have assumed that the albumen, supposed to be present, is not due to cystitis, which is a comparatively simple question to determine.

My general conclusion, therefore, would be: Rate up a young life showing albumen (if, of course, on general grounds you think it should be entertained at all) to an expectation of fifty-six or fifty-seven years; rate lives between, say, thirty and forty-five proportionately; and rate up heavily or reject altogether lives from forty-five to fifty years with this feature present. The question of offering an endowment policy, payable at fifty-five in such cases, is one for the Company's actuary. It seems to be another way out of the difficulty. The man who asks for such a policy to some extent favours the office at the expense of himself, since on the most favourable supposition he agrees to pay larger premiums than would be necessary at his age; and in the event of his death, say in ten years, the company would have received more from him than they would have done on an ordinary whole-life policy; while, of course, the chance of his death is not affected by the nature of his policy. But the question arises whether it would be fair to the other lives insured under the same endowment plan to admit invalid lives who might intefere with the prospects of bonus and profits to the other members of the class. For which reason I merely mention this plan as a suggestion, to be dealt with by the proper actuarial authorities. It seems to me, however, that the suggestions here made utilise facts which have been determined on a large scale, and over a long time, by actual experience, and so point the way to enable medical referees to offer more uniform advice to insurance companies, who may in turn adopt a more regular course in dealing with their clients in reference to this most important question.

A NEW ANTISEPTIC DRESSING.[1]

By Sir Joseph Lister, Bart., F.R.S.,
professor of clinical surgery in king's college.

Mr. President and Gentlemen,

When I last had the honour, five years ago, of addressing this society at the request of its president, I brought before you an attempt I had make to utilise the powerful antiseptic properties of corrosive sublimate, without the great disadvantages attendant upon its highly irritating qualities. I had ascertained that when corrosive sublimate precipitates albumen, the precipitate is not, as had been generally supposed, an albuminate of mercury, that is to say, a combination of albumen as an acid with mercury as a base; in other words, that the albumen does not displace the chloride from its combination, but that the bichloride of mercury retains its properties intact, the albumen being loosely associated with it, in a species of solid solution, if I may so say.

Further, I had found that this precipitate, even after drying, is capable of being dissolved in the serum of the blood, and that the solution in blood serum is powerfully antiseptic, while not irritating. I proposed and brought before you a new dressing in the shape of what was termed the sero-sublimate gauze, charged with a solution of corrosive sublimate in the serum of the blood. This gauze gave very satisfactory results, both in my own hands and in those of surgeons in places so far distant as Poland and Spain. Nevertheless, it was not all that could be desired by any means; it was somewhat harsh mechanically; it was not very absorbent, a serious defect, and one of the materials of which it was made, the serum of horse's blood, was not always easily obtainable. I was, therefore, well disposed to look for something superior.

A few weeks after that communication was made to the society, a firm of manufacturing chemists, Messrs. Gibbs, Cuxson and Co., wrote to me, saying that they had found that if chloride of ammonium or sal-ammoniac in quantity equal to one-fifth part of the weight of the bichloride of mercury was added to the mixture of bichloride of mercury and blood serum, the result was a much more fluid preparation than I had obtained. If I used a preparation of 1 part of bichloride of mercury to 100 of blood serum, I got a thick liquid somewhat difficult to diffuse in gauze. They therefore suggested that by adding sal-ammoniac in that proportion, I should get a much more workable arrangement. On consulting chemical works, I found that one-fifth of sal-ammoniac was exactly sufficient to produce with bichloride of mercury the salt long known to chemists as sal-alembroth, a double salt of bichloride of mercury and chloride of ammonium. I naturally wished to ascertain whether this addition of sal-ammoniac would impair or even destroy the antiseptic properties of the bichloride of mercury. I therefore made experiments on the point, and I found that the sal-ammoniac associated in the form of a double salt with the bichloride of mercury did not by any means impair its antiseptic properties; on the contrary, it improved them, so far at least as concerned that which we have to deal with as surgeons, an albuminous fluid like the serum of the blood. Sal-alembroth and bichloride of mercury proved to be exactly equivalent weight for weight as antiseptics in such a fluid. Each had to be used in normal serum of specific gravity of about 1025 in the proportion of nearly $\frac{1}{1000}$, in order to prevent altogether the development of micro-organisms. Those who

[1] Delivered before the Medical Society of London, November 4th, 1889.

are acquainted with Koch's researches will consider this a very high proportion. Koch has shown that in a solution destitute of albumen, $\frac{1}{100000}$ part of bichloride of mercury is sufficient to prevent the development of organisms; but when we have albumen present in the solution, the case becomes altogether altered. Albumen interferes with the antiseptic action of corrosive sublimate, and thus in serum of the blood of specific gravity 1025, we require, as I have already said, as large a proportion as about $\frac{1}{1000}$ instead of $\frac{1}{100000}$.

When the albumen is small in amount, less corrosive sublimate proves efficient. Thus in a case of spermatocele, where the specific gravity of the fluid was exceedingly low —only 1007—I found that $\frac{1}{10000}$, just intermediate between the proportions required for blood serum and water was efficacious. On the other hand, when blood-corpuscles are mixed with the serum in the same amount as in the circulating blood, making the albuminoid substances much more abundant than in serum, we require proportionately more of the corrosive sublimate; at least 1 to 500 is required for the purpose of preventing development. This is a most important consideration after an operation. In the first twenty-four hours the discharge contains a large amount of blood-corpuscles, as well as serum, whilst, at the same time, it is the most copious, more copious than it will be in any subsequent day, provided all goes well aseptically. It is, therefore, an exceedingly serious consideration, that in the first twenty-four hours we have a discharge which, in both these respects tests our antiseptic more severely than it will ever be tested again, both from its abundance and from its quality. Still the sal-alembroth, whether used with blood serum or with a normal mixture of serum and corpuscles, such as that obtained by whipping the blood of the ox so as to get rid of the fibrin, proved equivalent antiseptically to bichloride of mercury.

I may, perhaps, say in a few words how the experiments were conducted. For the purpose of ascertaining whether a given antiseptic can or cannot prevent development of organisms, a very simple mode of experimentation suffices. What we have to do is to ascertain whether it is *inhibitory;* not whether it is *germicidal.* The only special apparatus required for such experiments is a warm chamber, which can be kept pretty constantly about the temperature of the human blood. Beyond this, a few stoppered bottles, with well-fitting stoppers—perhaps half-ounce stoppered bottles —are really all that is required. Into a series of such bottles, serum of the blood, to the amount say of 150 grains, containing solutions of the antiseptic of different strengths is introduced. These are all inoculated by means of a small syringe pipette with the same quantity, say 1-10th of a minim, of some potently septic liquid, such as blood serum in a state of advancing putrefaction. The bottles are placed in the incubator, and then, if development takes place, that is evidence that in the bottle in which it occurs such proportion of the antiseptic as that bottle contains is inadequate; if no development occurs we have proof of antiseptic efficacy. The transparency of the serum permits a recognition of the development of the organisms, which invariably causes opacity. If we have no change in this respect, if the serum maintains its transparency, at the same time keeping its odour unimpaired, and further, if microscopic examination of any little sediment there may be shows that it contains no organisms, we have clear evidence that the antiseptic in the proportion concerned has proved efficacious.

Now, if the sal-alembroth was equivalent to the bichloride of mercury weight for weight, that shows that the sal-alembroth was really more efficacious as regards the quantity of bichloride of mercury it contained. The bichloride of mercury having the sal-ammoniac added to it, and also water in the double salt that is formed, is increased in atomic weight very considerably; and therefore if an equal weight of alembroth is equal in antiseptic action to bichloride of mercury, that shows that the bichloride of mercury is made more efficacious in the blood serum by the addition of the chloride of ammonium. The chloride of ammonium in combination protects the bichloride of mercury, so to speak, to a certain extent, from the interfering influence of the albumen.

At the same time, the sal-alembroth proved much less irritating than bichloride of mercury. Experimenting on my own skin, I ascertained that it has certainly not half the irritating property of corrosive sublimate. The chloride of ammonium attached to the bichloride of mercury, while it protects the bichloride in some degree from the influence of albumen interfering with its antiseptic operation, prevents it also from acting so powerfully on the human skin. And thus the union of sal-ammoniac with corrosive sublimate had the double advantage of rendering it both more efficacious antiseptically and much less irritating.

Hence I was at first much pleased with sal-alembroth. But it soon appeared that there were certain disadvantages attending it. These depend very much upon its excessive solubility. It is essential for a satisfactory antiseptic dressing that the antiseptic should not be readily washed out of it by the discharge. Sal-alembroth is so exceedingly soluble that it is washed out with the greatest ease; thus we were always, even if we used large masses of sal-alembroth gauze, in fear that when discharge was copious the antiseptic would disappear, say within the first twenty-four hours, and then the septic mischief would have an opportunity to enter. There was another disadvantage from this great solubility. When the discharge entered a mass of the sal-alembroth dressing it dissolved out the alembroth from it, passed into another part of the dressing, and there took up another portion of the sal-alembroth, and so went on from part to part of the dressing, until if the discharge was copious and the dressing large, as it must be when the discharge is copious, before the discharge got to the edge of such a dressing it became so concentrated a solution of the sal-alembroth as to be highly irritating. We have seen, for instance, after the removal of the mamma, when the first dressing is changed on the following day that there has been over the scapula and the neighbourhood a huge blister. No doubt that was only a temporary inconvenience. We never had the discharge again so great as in the first twenty-four hours; but still it was a great inconvenience.

Such being the disadvantages of sal-alembroth dressing, I was disposed to seek for something better. I may say that I myself have never published anything in favour of sal-alembroth dressings; I have never been satisfied with them. It has leaked out that I have used them, and they have come into extensive employment, but never with my published sanction.

In the course of the following year I made various experiments, in the hope of rendering sal-alembroth more useful in different ways, with which I need not trouble you, but without much success. In February, 1886, my attention was drawn by Mr. Martindale, of New Cavendish-street, to cyanide of mercury as possibly a valuable antiseptic, and, if so, having this advantage—that it did not coagulate

albumen. I therefore proceeded to make experiments with cyanide of mercury, and I found indeed that in inhibitory power it was remarkably efficacious. I have said that with blood serum sal-alembroth or bichloride of mercury is required in about $\frac{1}{1000}$th part. I found that the cyanide of mercury kept blood serum, with only $\frac{1}{10000}$th part, perfectly free from organic development, in spite of inoculation with potent septic fluid, for a month, when the experiment ended. I may remark that we have in cyanide of mercury a striking instance of the discordance that there may be between inhibitory power and germicidal power in an antiseptic. In inhibitory power the cyanide of mercury is, as we have seen, exceedingly high; but in germicidal power it turns out to be very low. Mr. Cheyne has made experiments for me, which have shown that even $\frac{1}{1000}$th part in water is incapable of destroying the germs of bacteria. Still the inhibitory property of cyanide of mercury was a most important point, if in other respects the salt was not disadvantageous; but, unfortunately, it proved to be so highly irritating, that the greater irritating property of the cyanide of mercury more than counterbalanced its superior inhibitory power. It naturally occurred to me that the cyanide of mercury might perhaps combine with some other cyanide and form a double salt, having advantages corresponding with those presented by sal-alembroth as compared with bichloride of mercury. I tried the soluble double cyanide of mercury and potassium, but found it quite too irritating. I here again consulted Mr. Martindale, and he mentioned to me that in Watts's *Dictionary of Chemistry* it is stated that a double cyanide of mercury and zinc of very slight solubility may be formed by mixing together a solution of the double cyanide of mercury and potassium with a soluble salt of zinc, the zinc taking the place of the potassium. I therefore obtained some of this material, and proceeded to make experiments on it. I ascertained, in the first place, that it was quite insoluble in water. This seemed at first extremely unpromising. It was soluble in about 150 parts of glycerine, but insoluble in water. I found, however, that it was soluble in about 3,000 parts of blood serum, and therefore it was possible that it might work antiseptically. I made experiments to ascertain whether such was the case or not, and I found that this zinco-cyanide of mercury, as we may call it, had really most important antiseptic properties; that in the proportion of 1-5000th part it kept blood serum perfectly free from the development of organisms for eighteen days, in spite of potent septic inoculation.

I then tried experiments with serum and blood corpuscles as presented in the whipped blood of the ox. On instituting comparative experiments between sal-alembroth, all proportions lower than 1-400th putrefied within twenty-four hours after septic inoculation, while with the cyanide of mercury 1-800th part sufficed to preserve the serum and corpuscles from putrefaction. At the same time with the double cyanide I was much surprised and much pleased to find that 1-1200th, half as little again, was sufficient to keep the mixture of serum and corpuscles permanently free from putrefaction. It may be said that the absence of putrefactive odour is but a rude test. There may be organisms developed without any putrefactive odour being present; that is perfectley true. At the same time, if in a given experiment we find that with one agent putrefaction occurs within twenty-four hours with 1-400th part, while with another salt there is no putrefactive odour after a lapse of weeks with 1-1200th part, we have pretty conclusive evidence that, so far as the mixture of corpuscles and serum is concerned, we have a more efficacious antiseptic in the latter. I therefore proceeded to prepare dressings of this new substance, diffusing it—for it is an exceedingly fine powder—in water, with a little glycerine added to fix it, to prevent it from dusting out. If you simply diffuse it in water and pass gauze through it, with nothing more than the water, the resuls is that you have gauze which, with the slightest touch, gives out the double cyanide in a cloud of dust, which produces not only inefficacy of your dressing by loss of the proper proportion of the substance, but becomes in the highest degree irritating to the nostrils of those who are near. A little glycerine, however, prevented the double cyanide from thus dusting out. I proceeded to try it in practice. I confess I did not dare to use it—considering its very slight solubility in serum—unmixed, and I associated with it some of the very soluble cyanide of mercury; and with this cyanide gauze we tried various experiments in the way of dressing and got some admirable results. But then, on the other hand, there were disappointments. We found, for one thing, now and then very troublesome pustules, as the result of a peculiar kind of irritation. Another disadvantage was that occasionally we got suppurations, coming on at a late period in the case, such as we had never been accustomed to with our carbolic dressings. A case might go on perfectly well for, say, ten days, and then suppuration might occur about a stitch track and spread perhaps further; and sometimes the healing of cases was greatly protracted by this late suppuration. In consequence of these two circumstances I gave up the use for the time being of this material.

I then directed my attention to biniodide of mercury, which has been highly spoken of for its antiseptic powers, and which has the advantage over alembroth of being comparatively little soluble either in water or in serum. I found that the iodide of mercury gauze answered our purpose very well so far as its antiseptic properties were concerned, but that it had the great disadvantage of producing irritation, which it was extremely difficult to control. In order to control it we interposed between the iodide of mercury and the skin, unprepared gauze, except in so far as it was steeped in a weak solution of bichloride of mercury (1 to 400). But we found that different skins differed greatly in liability to this irritation. The iodide of mercury, which is so very slightly soluble, as you know, in water, is much more soluble in serum, and the solution in blood serum becomes irritating. In consequence of this we had the same disadvantages from irritation as we had with the alembroth; and although, as in the case of the alembroth, this was only a transient inconvenience, I became dissatisfied with the iodide of mercury gauze. There was, however, one point of considerable interest, both theoretically and (as it turned out afterwards) practically, which we found in this investigation with the iodide of mercury. If we simply charged with iodide of mercury, say from a solution in spirit of wine, and then applied the gauze so prepared, we found that the particles of iodide of mercury tended to gravitate down towards the skin, and there produce the most fearful irritation. It was absolutely necessary that it should be fixed. I tried various means, and among the rest a solution of starch, and then there came out this remarkable fact, that if a solution of starch is used with one of the ingredients employed for forming the biniodide of mercury by mixing a solution of iodide of potassium with solution of bichloride of mercury—if you dissolve the iodide of potassium in a

weak solution of starch—the iodide of mercury thus formed in the nascent state associates itself with the starch particles in the most intimate manner, and becomes entirely precipitated along with the iodide of mercury. If you take a drop of the red fluid formed by mixing these two solutions, and place it on a piece of calico, the watery material is absorbed by the calico, and passes into the surrounding parts without colouring them, while the red spot with its insoluble iodide remains.

If now you take a little iodine water, and apply it to the part of the calico moistened by the fluid that has exuded, you find that the iodine water produces no blue colour of iodide of starch, showing that there is no starch in the fluid that thus oozes out, and leaves the iodide of mercury behind; whereas, if you take a simple solution of starch and apply it as such to a piece of fabric, as far as the fabric becomes moistened so far do you get a blue colour with the iodine. Here we have, as it seems to me, a somewhat analogous case to the so-called albuminate of mercury. We have the starch particles associated with the particles of iodide of mercury; the starch remains as such, the iodide of mercury remains as such; still they are attached to each other. As so the result was that when such a red solution produced by mixing these two liquids was used for charging gauze, the iodide of mercury was stuck to the gauze by means of the starch, and we had a most satisfactory arrangement in that respect. The iodide of mercury could not be washed out by water, nor did it in the least dust out. The value of this observation with reference to our present subject will appear shortly.

Being dissatisfied with the iodide of mercury, I turned my attention again to the double cyanide of mercury and zinc. Looking back to my notes, I found such evidence of its superior antiseptic properties that I felt that we had deserted this material too readily. In the interval we had had other experience of importance with the alembroth gauze. Occasional late suppurations had at first occurred under its use, just as was the case with the double cyanide gauze. These, however, had ceased to trouble us after my attention had been directed to the expediency of always using mercurial dressings in a moist condition. If they are used dry, the mercurial salt having no volatility, and having no power therefore of destroying any micro-organism in contact with it, whether derived from the manufactory or elsewhere, there could be no security that the dressing when applied was free from living organisms. This important object could, however, be infallibly attained if the dressing were used moist with an efficient germicidal solution. I put this idea in practice, and during the two years that have since elapsed, we have never on any single occasion had to complain of these late suppurations. Might not the same immunity attend our cyanide gauze if we adopted with it the same expedient?

The other objection to this double cyanide gauze had been the irritation which it occasioned. Might not this have been due to the simple cyanide, which, as I have said, I used along with the double cyanide? The simple cyanide is highly irritating, and, just as with the sal-alembroth, being freely soluble, it can be taken up by successive portions of discharge, and, when the discharge is free, may come to be in so strong a solution as to irritate. On the other hand, experiments on my own person had shown that the powder of the double cyanide might be kept applied to the skin for an indefinite time, whether moistened with water or with blood, without occasioning any irritation whatever. If this was the explanation, and if, as our experiments indicated, the double cyanide could be trusted, we might get rid of irritation by using a double cyanide dressing moistened with a weak solution of bichloride, say 1 to 4,000, which, while it is securely germicidal, can never irritate. But here arose a new difficulty. I have told you that when we tried this double cyanide in a gauze at first, in order to prevent the dusting out, with its great inconveniences, we used glycerine; but if we moistened the gauze with 1 to 4,000 solution of corrosive sublimate, we should run great risk of washing out the glycerine, and then the double cyanide would be free to dust out on drying. And, besides that, it must be admitted that the glycerine arrangement was not a good one, independently of that consideration, inasmuch as when the discharges flowed into the gauze they would wash away the glycerine, and then the double cyanide might be washed out also, and so fail in one of the most important requisites of an efficient antiseptic dressing—the storage of the antiseptic in the dressing in spite of the discharge. How was this difficulty to be overcome?

Now came to our aid our experience with the iodide of mercury and the starch. Might it be that the particles of the double cyanide might attract starch as those of the iodide had done? It did not seem very likely, seeing that cyanogen is not known to have the special affinity for starch that iodine has. Still, I though I would try the experiment. I prepared the double cyanide by mixing a solution of the double cyanide of mercury and potassium with a solution of sulphate of zinc. I tried this with one of the ingredients dissolved in a starchy solution; and, to my great satisfaction, I found that the precipitated double cyanide left a supernatant liquor almost absolutely free from starch, and that the particles which thus fell, the double cyanide with the starch associated, fixed themselves to a gauze in such a way that it did not in the least dust when dry. Not only so, but immediately after being charged with the precipitate diffused in water, it might be washed in the wet state without the double cyanide being washed out of it, so closely did the starchy particles stick the double cyanide to the fabric. It is of great importance that in some way or other the double cyanide should be washed, because at the same time that an insoluble double cyanide is formed, there are produced other double cyanides which are soluble, and which are in the higest degree irritating; they must be washed out.

Well, I thought I had thus obtained my object, and that by mixing starch with one of the two solutions necessary for forming this double cyanide and allowing the precipitate to fall then decanting, pouring in more water, and, after precipitation, decanting and repeating the process another time, so as to get rid of all the irritating soluble salts, and then diffusing the precipitate though a gauze I should have all that I desired. But when I tried to get this done commercially I found that I got such blundering as to make the thing practically hopeless. There was nothing for it but in some way or other to get the double cyanide from the chemist as a definite product, and then in some way devise a means of fixing that powder of the double cyanide to the fabric. I therefore naturally tried whether a solution of starch would answer this purpose; whether the starchy particles would associate themselves with the double cyanide particles, not only in the nascent state, which we had before tried, but also when the already formed double cyanide was mixed with the starchy solution was stirred up with the double cyanide in the proportion of one part of starch to two of cyanide, the starch was

almost all precipitated, and the precipitate so formed adhered to the gauze in the most satisfactory manner.

But though its adhesion was satisfactory enough, it turned out that the precipitate thus formed aggregated into a tenacious mass, which could not be diffused uniformly through the gauze, and here I was again at fault. This difficulty was overcome by first charging the gauze with the double cyanide powder diffused in water, and then transferring it to a starchy bath. This at once fixed the cyanide in the gauze: and whereas, before it was placed in the starchy bath, the slightest squeeze made a milky fluid exude, no sooner had it been well penetrated by the starchy liquid than you might squeeze it as you pleased, and nothing came out but a clear fluid. I was much pleased with this, and it is in this way that I have prepared the gauze that I have used for the last twelve months, both in the hospital and in private practice. Still, this method had its disadvantages. When the gauze had been passed through the fluid in which the double cyanide had been diffused without any starch, it required very tender handling. If you gave it a squeeze, out came a quantity of double cyanide; and it was plain that, although one might do it one's self satisfactorily, if we trusted to the manufacturers, there would be an utter uncertainty as to what quantity of material might ultimately remain in the gauze.

Only lately has this difficulty been surmounted. It occurred to me that perhaps if the starch were first blended with the double cyanide, and then dried and reduced to powder, if water were afterwards added to this dried dissolved starch associated with the cyanide, there might not be the same tendency to lumpiness and difficulty of diffusion. I found that the process did not answer quite as I hoped in the first instance, in this respect, that the dried starch and double cyanide were extremely difficult to scrape off from any plate on which they were put to dry, and also very difficult to pound up and to diffuse for charging the gauze. I got rid of these inconveniences by means of sulphate of potash, used for the same reason as Dover's powder—that is, that it is an inert substance, with sharp, gritty particles. Mixing a pretty strong solution of starch with the double cyanide powder and adding to this a quantity of pounded sulphate of potash, the result is that you get a material which, after drying, is easily scraped off by the manufacturer and easily reduced by him to an impalpable powder, which is then readily diffused in water, and makes a perfectly uniform gauze. Being mixed in large quantity with water in order to charge the gauze, the sulphate of potash is practically got rid of, and if any of it remains it does no harm, because it is inert. Thus we have the means of easily charging fabrics with this double cyanide.

I have spoken of diffusing this preparation in water, but in reality we employ for this purpose the 1 to 4-000 solution of bichloride of mercury, which fortunately does not in any way interfere with the process. I may remark that the double cyanide, like the simple cyanide of mercury though very efficient as an inhibitor, cannot be trusted as a germicide. There are different ways in which absorbent gauze such as this may be charged. One is to pass it folded in about sixteen layers through a trough, such as the one before me, which I myself used, having a bar near the bottom to ensure the gauze being kept well under the liquid. It is then, as soon as you please, squeezed, to press out superfluous liquid, and then if wanted for immediate use, a simple way is to place the masses of gauze—say, six-yard pieces—in a folded sheet, turn the folded sheet over then and roll it up. The folded sheet then absorbs the still redundant liquid, and you have moist gauze ready for use in five minutes. For the use of the ordinary surgeon it will probably be best to have the gauze dried, on the understanding that it is again moistened with 1 to 4,000 sublimate solution before being used. Here is a sample of the gauze in the dry state, which you see does not give off dust even when freely handled.

Other articles may be charged as well as gauze with this substance. The double cyanide being perfectly unirritating, there is no objection to having an excess of it. If you take therefore some of the preparation and stir it up with water, so as to produce an opaque liquid, and put linen rags into it, and then place them in a folded towel to take out the excess of liquid, you have your dressing ready prepared then and there. It can thus be very easily worked on an emergency.

We have seen that the double cyanide requires about 3,000 parts of blood serum to dissolve it. If therefore it is present in a gauze in the proportion of about 5 per cent., you will easily understand that blood serum may soak through such a gauze time after time without washing the ingredient all out; so that it is a material which is admirably stored up in the dressing. That is one of the three great advantages, the others being that, while trustworthy as an antiseptic, it is competely unirritating. In actual practice the few layers placed next to the wound are washed in a solution of carbolic acid, 1 to 20; this washes out the corrosive sublimate, which, though present in small amount, might irritate the wound to some extent. The carbolic acid soon flies off, and there is left in the application next the wound merely the unirritating double cyanide, and under this we find that not only do wounds, the edges of which are brought accurately together, unite beautifully by first intention, but even granulating sores heal by the gradual process of cicatrisation from the edges —heal by scabbing in a way that we have never seen so satisfactorily under any other dressing.

Having satisfied myself that this was really a useful material, I proceeded to request a manufacturing chemist to provide it for me on a large scale. Messrs. Morson and Son, of Southampton Row, kindly undertook to do this, and I have to thank them for the great pains they have taken in carrying out experiments on this subject at my suggeston. Their manager, Mr. Taubman, soon informed me that in his opinion there was exceedingly little mercury in this so-called double cyanide of mercury and zinc. Very little mercury could be got from it on testing, in comparison with what he obtained if it were a true double salt. He asked if I was sure that the cyanide of zinc was not after all the thing that was efficacious! Was the idea of the double cyanide altogether a delusion? I need not say how much pleased I should have been if such had been the case—if we could have had the cyanide of zinc without any poisonous mercury in it as an antiseptic. The cyanide of zinc was a perfectly definite compound, there could be no mistake about it. I proceeded to make experiments, and I found, indeed, that cyanide of zinc has antiseptic properties. I made, for instance, experiments of this kind—I took a piece of glass tube and packed it in two inches of its length with gauze charged with cyanide of zinc only, and then, holding it vertically, poured serum of horse's blood into it till the gauze was fully moistened; and then poured more in, till a quantity dropped out from the lower end equal to that which had produced saturation, the upper part of the gauze being thus thoroughly washed with the serum.

I then inoculated the top of the gauze with a potent septic drop. I had another similar tube with gauze that had no cyanide of zinc in it, and after pouring serum through it I inoculated that. I put each into a stoppered bottle, so as to prevent any evaporation, and placed them in the incubator. At the end of four days I opened the two bottles. That which contained the gauze without the cyanide of zinc stank, and, on taking portions of the gauze from either one end or the other, squeezing them and examining under the microscope the fluid that escaped, there were seen teeming multitudes of bacteria of various sorts. The bottle with the cyanide of zinc, on the other hand, had a pure odour of hydrocyanic acid, which this gauze always has when moist. I then examined drops squeezed from both ends, and I found no bacteria in the clear serum that was pressed out, not only from the lower end, but even from the upper end in the immediate vicinity of the inoculating drop, and where the gauze had been drenched repeatedly with the serum.

Now that, so far, is a result such as no other antiseptic had ever given me. Take iodide of mercury, for example. Comparatively insoluble as it is, if you pour blood serum upon it in such profusion you wash the iodide of mercury out, and if you inoculate septically the part so washed you induce bacteric development. The test applied was, of course, a severe one. In actual surgical practice the discharge which pours into the dressing is pure to begin with, supposing the wound to be aseptic at the outset. The septic agency acts from without upon unwashed parts of the dressing, and in a far milder form than here, where a potent septic drop was used. Thus we had clear evidence that the cyanide of zinc is an antiseptic. On the other hand, it turned out to be not so powerful antiseptically as our double cyanide so-called. In order to compare the two salts I made another experiment similar to that last described. I packed three pieces of glass tube with gauze in two inches of their length, one of the gauzes being charged with cyanide of zinc, and another with the so-called double cyanide (neither of these gauzes having been treated with solution of bichloride of mercury), while the third gauze was unprepared. Serum of horse's blood was poured into the upper end of each vertically-held tube till it thoroughly soaked the mass of gauze, after which each gauze was inoculated septically as the centre of its upper end. The tubes were then placed vertically in stoppered bottles in the incubator. It happened that in the septic liquid used for the inoculation that I used there was, among other organisms, a species of streptococcus which had a remarkable power of producing an acid fermentation in blood serum. After four days I proceeded to examine the contents of the three tubes. In the unprepared gauze there was utter putrefaction. In the gauze prepared with cyanide of zinc only, no putrefaction had taken place, but acid fermentation had occurred; both at the upper and lower end of the gauze litmus paper was reddened on application to the serum. In the putrid gauze turmeric paper was most intensely reddened, much more so than by normal blood serum, an alkaline fermentation having occurred there. On the other hand, with the gauze that contained the double cyanide, with mercury as well as zinc, both at the upper and at the lower end in the turmeric paper was reddened exactly as it was by the normal blood serum. This state of things continued the next day; but on the following day, six days after the commencement of the experiment, I found that at the upper end, in the vicinity of the inoculated spot, this gauze purpled litmus; while at the lower end it still reddened turmeric. At the end of seven days the same condition persisted. After eight days, however, both the upper and lower end of the gauze purpled litmus.

This peculiar septic organism, with the power of producing acid fermentation in the serum, had gradually worked its way down, in spite even of the cyanide of zinc and mercury; but the cyanide of zinc and mercury, you observe, had been much more efficacious than the cyanide of zinc alone. The cyanide of zinc had prevented the development of organisms that produced putrefaction, and only permitted the growth of the coccus that produced acid fermentation. Cyanide of zinc and mercury had for several days prevented all development. This was proof, therefore, that the mercurial element in our compound was valuable, and that we could not dispense with it.

It may be thought an unsatisfactory thing that there should have been any organism able to work its way thus through a gauze charged with our antiseptic. But I may remark, in the first place, that, as above stated, we tested the material exceedingly severely; in the second place, that it was a long while before the organism penetrated the gauze even for a short distance; and, in the third place, that penetration of micro-organisms through such a dressing into wounds does not seem to occur in practice, seeing that in the year during which I have used this antiseptic in my surgical work at King's College Hospital we have had no single instance in which we have had any reason to suspect septic change in the deeper parts of our dressing; we have had no instance in which deep-seated suppuration has occurred in an operation wound made through unbroken integument. If we have had any pus at all in such cases it has been from the surfaces exposed between stitches, or at situations where drainage-tubes have been inserted, where what I have termed antiseptic suppuration has shown itself occasionally, and even this in very slight degree. Such being the case, I feel not only permitted but bound to bring this material under the notice of my professional brethren.

As to the composition of this so-called double salt, it is for the present uncertain. This much is already established: that the cyanide of mercury is in very much smaller proportion to the cyanide of zinc than Watts's *Chemistry* would lead us to expect the double salt would give. But what the precise composition of the salt is we do not yet know. I am having it investigated by the Pharmaceutical Society, who have kindly undertaken the work.

There is another use for this material besides the charging of dressings. The powder moistened with a weak solution of corrosive sublimate may be rubbed into hairy parts, where it will convert the hairs into an antiseptic dressing. Not long ago a medical friend of mine brought his wife to me with no less than seven sebaceous cysts in the scalp, requesting me to remove them. Having washed the hair with 1 to 20 carbolic acid solution, I simply passed a comb over each tumour in the line where I was about to transfix, without shaving at all; and after taking out the cysts, rubbed some of the moistened powder into the hair in the vicinity. I then applied a dressing of cyanide gauze, and I was glad to learn that all the seven wounds had healed without disturbance.

We have now in the hospital a case of psoas abscess, shown to be of spinal origin, not only by the history of the case and the symptoms, but by the discharge of a portion of bone with the pus. That case is pursuing a course which, allow me to say, psoas abscesses will pursue in the

great majority of cases, if the surgeon uses a trustworthy antiseptic, and takes the same pains with dressing to the last as at the outset; that is, he will find his trouble rewarded by the complete cure of these formerly incurable cases. I say this because I grieve to think that psoas and lumbar abscesses still seem to be regarded as hopeless affairs by many surgeons. In this man's case the temperature has never been affected in the least; he has put on flesh rapidly; the discharge. after the purulent and curdy matter that existed originally in the abscess was got rid of, has been of serous character, and is in small and diminishing quantity. But the opening made for the discharge is in the vicinity of the pubes, and the pubic hairs used, under such circumstances, to be a constant source of anxiety unless frequently shaved away. Here we rub in at each dressing a little of the moistened cyanide, and convert the hairs into an antiseptic application.

I will not at present enter into the details of the preparation of this material; these will be supplied in a note on a future occasion.

The sketch which I have given you of this investigation, though it has, I fear, wearied you, conveys but a small idea of the toil it has involved. There are those who still believe that the use of antiseptic substances in surgical practice is always useless, if not injurious. The germ theory of septic diseases is indeed now happily established incontrovertibly. All now admit that septic mischief in our wounds depends upon the development of micro-organisms in them derived from without. But the gentlemen to whom I refer are, more or less logically, disposed to trust everything to the antiseptic powers of the human tissues.

I believe I happened to be the first to direct attention to the antiseptic agency of living structures, and there is perhaps no one who attaches greater importance to it than I do. Without it surgery in former days would have been absolutely impossible. Still I know too well from experience that it cannot always be trusted, and that the use of antiseptic adjuvants is in the highest degree important. And I have the satisfaction of knowing that there is among you a constantly increasing number who, when they have operated on an unbroken skin, with a fair field around for the application of their dressings, if they see septic inflammation occurring in the wound with its attendant dangers, know that it is their fault, or the fault of the antiseptic appliances at their disposal. To those among you who are impressed with this conviction I offer the dressing which I have described as the most satisfactory that I have hitherto met with; and I venture to hope that you will regard it as a not unwelcome addition to your resources.

THE REMOTE CAUSES OF PELVIC DISEASE.

By John F. Le Page, M.D.

Within the whole range of medical science there is no branch which, in its far reaching importance, can compare with that which embraces those diseases in women, which originate in her pelvis; and, notwithstanding the large experience and the unquestioned competency of the average general practitioner, I have no hesitation in saying there is no department of our science in which he is less perfectly informed—on which he has less definite and practical views. Probably this anomalous condition of things is due in part to the altogether erroneous idea that it constitutes the special domain of the gynæcologist; and, perhaps, it is, in a measure, owing to the fact that in his student days his college ignored the very existence of gynæcology, save as an insignificant appendix to midwifery. It is not a little strange that diseases, important in themselves, but even more important because of their endless effects on the economy, and their influence on the very essentials of life, should, almost up to the present day, have received the scant attention accorded them. Every man who practises medicine should be a gynæcologist; and it is difficult to understand how he can be a competent practitioner if he has not carefully studied those diseases which have their origin in the pelvis of woman, for not a day passes on which he could not trace cases, too often treated on general principles, to a remote cause born and nurtured in the pelvic organs.

The subject is so exceedingly large that I cannot hope, and do not propose, in the compass of this paper to touch on but a few of the very many causes which influence the integrity of pelvic health, nor shall I refer to the secondary causes, on which there is an abundance of literature, which constitute the usual starting point. I will further limit my remarks to an etiology which is peculiar to woman, as contrasted with lower orders of female life, and of enquiry which develop conditions not found in the female of those orders.

If one system in woman is peculiarly liable to perverse action, and that system in other mammals is not prone to deviations from normal function, there is *primâ facie* ground for the presumption that in woman causes exist which do not operate in other animals. The key is found in the comparative physiology of their generative systems. In what principal regards does woman differ physiologically from other females? Woman menstruates; no other female but that of the monkey has a true menstrual cycle, although some have, occasionally and at irregular intervals, a pseudo-menstruation. Woman ovulates at short and regular periods, and is capable of induced ovulation at almost any time. The lower orders ovulate after intervals very much longer relatively to the average duration of their lives, and during these long intervals their ovaries are quiescent. Woman has no quiescent period. Her ovaries are, during the whole of the thirty or more years of her menstrual life, in a state of functional activity. She, in common with monkeys, but no other animal, has a lochial discharge. She expels not only the fœtal placenta but the maternal placenta also passes away by the vagina. Ercolani has shown that this mode of removal is peculiar to upright animals. In others it is absorbed by the lymphatics.

Woman's placenta is a complicated organ, and its formation is an elaborate process as compared, for instance, with that of the diffuse placenta of the mare. In proportion to the complexity of this organ is the period which elapses *in lower animals* before the return of rut, and the lower the animal the shorter is the time occupied by the terminal of the cycle—the reconstruction of the uterus. The anti-rut—a period during which sexual appetite is absolutely dormant—does not bear any fixed proportion to the grade. But in almost all, rut or sexual activity, is of short duration; anti-rut or sexual repose is prolonged. In woman the equivalent state to rut is unending. There is no interval during which the sexual instinct is in abeyance. It seems almost inevitable, in view of this disparity, that, pathologically compared with the lower animals, we find woman subject to an endless train of disorders, infarctions, and neuroses, which in them are entirely unknown. The proneness of woman to disorders of, or dependent on, or

having relation to her generative functions, is due to the persistence of her sexual activity without intermission, and with scarcely remission, through both the cycles of menstruation and fœtation reacting on a more complicated and more highly sensitive nervous organism than is found in any other mammal.

The life of a woman naturally divides itself into three periods: The pre-menstrual, the menstrual, and the post-menstrual. Many of her diseases may be traced to the first period, the whole of which is occupied in the development of the organs of sex. With its close ends the process of physical development generally, although growth may continue for years. In the construction of any complex mechanism the greatest care is evinced in the accuracy, the completeness, and the stability of the detail; and its subsequent state of competence to meet the ends for which it is made, its usefulness and efficiency depend largely on the care which has been bestowed in its formation: and, in like manner, the healthy, the efficient, the perfect development and growth during this first period, is dependent to a large extent on the relation of external influences to that development. If the process is allowed to go on as best it can, with ever active opposing influences exciting unrestrained tendencies to eccentric development and deviations from normal standard; with the bias of the habits and customs of an artificial society, the natural result is a development stunted in its completeness, or ill-balanced in its detail. Over-developments ready to exercise an unwonted sway; under-developments calling for the exercise of the law of compensation.

The failure to physically educate girls during this all important formative period lies at the very root of the evil. Exercise is absolutely essential to development, and to the activity and regularity of function. Muscle, both voluntary and involuntary, owes, not only its growth, but its continued efficient existence to its exercise. If disused for a time it wastes, as seen in the flaccidity and diminished calibre of the muscles of a fractured limb. If unused for many generations, it becomes rudimentary—of this we have many examples. Even the fœtus in utero, untutored but by instinct, daily exercises its muscles; whilst the uterus all through pregnancy, contracts rhythmically every few minutes; these contractions, this uterine exercise, being essential to its development. It is my belief, and, from observations I have been able to make, that belief has grown into a conviction, that not only some but *all involuntary muscles are subject to rhythmic contractions*. The rhythm is not synchronous; in some it is long, in others short; nor is the duration of contraction in a ratio to the interval. Both are proportioned, first, to the effect required on the economy, as in peristaltic movements; secondly, to the requirement of the maintenance simply of passive efficiency, as may be observed in the long rhythm of the cremasters; thirdly, to the requirements of active development, as evidenced in uterine muscle during gestation. *Voluntary* muscles have no rhythm, but, given that all *involuntary* muscles are subject to an inherent proneness to rhythmic exercise, is it possible to argue—certainly not from analogy—that striated muscle can develop, and mature, and become educated, and maintain efficiency without a system of exercise such as that which is natural to all the nonstriated? Muscular inherent contractility, dependent in health on the stimulus of well oxidised blood, furnishes the incentive to restless movement during the first few years of life, until the strain put on the brain by forced study, and the total absence, in most cases, of any calisthenic training, destroy the incentive to exercise. This premenstrual period is essentially the time for education. Everything is maturing; everything needs culture and training. But the modern system of so-called education, fulfilling the requirements of a false and exacting society, is at the very root of the evils initiated in this period. Society claims a standard of literary knowledge in girls attainable, in the majority, only by mental strain and cramming, and environed with an utter disregard for the laws of life, with the result that girls grow to womanhood with cultured brains, but with a highly wrought and sensitive nervous system tyrannically dominating all other systems, which are mercilessly at its service. This is ill repaid by her ability to dispute with men, and to assume a bastard manliness. Education should be thorough, but it should be the education of the whole organism, the development of all its functions, that a healthy and well balanced physical organisation may give direction to a cultured mind. The devoted disciples of æsthetic philosophy may revel in ability to discourse in Latin; to translate sensational, if not lewd, Greek plays; or to enter into dissertations on funicular polygons; but the seeds of disease are sown in themselves, to bear abundant fruit in those who are so unfortunate as to be begotten of them.

The custom of covering portions of the body with numerous layers of non-conducting materials, such as wools, whilst the extremities are left bare, or very lightly clad, has undoubtedly a mischievous tendency. I have found the surface temperature vary, in differently clothed parts of the body, as much as 30°F. This, of course, means that in the exposed parts there is a deficiency of blood, and a slowness of circulation in the constringed vessels, with a passive engorgement of the portions—to wit, the lumbar portion of the spine and the abdomen—which by reason of their unwonted warmth have dilated vessels and an inordinate blood supply. The effect of this condition of things as a factor in the genesis of pelvic dyscrasia, existing as it does through the whole period of pelvic development, calls for a far stronger protest from our profession than has hitherto been made. The rapid march of medical science over tends to allure from the platitude of fundamental minutiæ.

The food of the growing organism should contain a large proportion of inorganic material in addition to the albuminous and carbonaceous substances which compose the multitudinous compounds of the modern *cuisine*.

In the menstrual period, bounded as it is by two epochs—the maturition of the sexual organs and the decadence of generative functional activity—an important fact stands out. It is that nearly every one of the pathological conditions found in the sexual organs can be traced back to one and the same primary morbid state. That is to acute or chronic, local and circumscribed or diffused hyperæmia or inflammation of the uterus, the ovaries, or the tubes. Then how is it that the pelvic organs are so prone to congestion? Because they have very large and important nerve centres with reflexes almost *ad infinitum*. Because they have a richer blood supply than any other organ. Because the calibre of their blood-vessels is influenced by the mind in a degree out of all proportion to mental influence on any other organ, and because their functions are peculiarly liable to irregular, incomplete, or perverted action. Among the causes which operate during this period are gonorrhœa, hysteria, missed organism, and in neurotic women an exalted state of sexual feelings with perverted instincts tending to moral insanity. It is difficult to overestimate the

far-reaching importance of gonorrhœa in the female. Without admitting, or attempting to disprove, that the invariable presence of the gonococcus furnishes in itself proof that it is the specific cause of the disease, or that this gonococcus is simply one of the germs which in countless legions pervade all things, and comes into active existence, simply because the gonorrhœal poison furnishes the particular matrix in which alone it can develop. The fact remains that commencing in the vagina gonorrhœa rapidly involves the cervix; and the cavity of the uterus, the tubes, and the peritoneal cavity are not infrequently implicated, often causing endless troubles, and greatly interfering with the health, and by secondary effects often influencing the life of the patient.

The neurosis which we still recognise under the misnomer "hysteria," unknown to the science of morbid anatomy, of the existence of which we have cognisance solely by its multifarious, its heterogenous, and its marvellously capricious manifestations, is a disease of nerve centres, the peculiar characteristic of which is its simulation in turn of almost every other disease, its mimetic effects producing pseudo diseases *ad infinitum*, accompanied by hyperæsthesia and anæsthesia, frequently by perversion of the intellect and exaltation of the emotions. In it the functions of nerve centres are so deranged that centric hyperæsthesia gives rise to false impulses and incoherent reflexes which derange the whole mechanism of life. If the phenomena of hysteria are dependent on centric excitement due to, or causing, hyperæsthesia and hyperæmia, and to the aggravation of the consequent loss of balance by the contiguity of areas in a condition of exalted nervous and vascular tension, to areas under opposite neurotic influences, causing anæsthesia and anæmia, then it follows that, that part of the body, the pelvis, which has at once the largest centres and the most important reflexes, and which from many causes is most liable to neurotic excitement and inordinate blood supply, will afford a vantage ground for the full play of this neurosis. Probably it is here in a large proportion of cases that the disease originates, as it is also here that its worst effects are seen. At the very root of the morbid conditions which originate in the pelvis is incomplete or missed orgasm. The sequence of events in the cycle of the physiological process referred to commences with psychical stimulation of the cerebro-spinal centres, or reflex impulse from the sacral plexus causing inhibition of the vaso-motor by impulse of vaso-inhibitory nerves, and giving rise to local hyperæmia, evidenced by general turgescence of vulva, uterus, tubes, and ovaries, distension of erectile tissue and the activity of Duverney's and the thousand or more sebaceous glands. The return to the *status quo ante* is effected by the apposition of the fimbriæ of the fallopian tubes to one or other or both ovaries, and the almost immediate effect is an impulse, the reflex of which is vaso-motor excitation, causing local vascular deplition, and return to the conditions antecedent to orgasm. Chiefly due to causes which are virile, and for which she is not responsible, this return does not in many women supervene; and it needs no argument in proof that if a tangent is continually struck at congestion, and this unrequited pelvic hyperæmia is repeatedly renewed, pelvic disease may, and indeed does, often result.

The customs of society, and the environments of the everyday life of woman, furnish countless incitements in many to, and foster, and develop, an exalted state of sexual instincts which, if not restrained, sometimes give a bias to the mind, which rapidly subdues the moral sense. In those cases, disease is probably originated in the genito-spinal centre of Büdge, at the level of the fourth lumbar vertebra, and extends to the anterior and posterior cerebral cortex; reacting on the genito-spinal centres, vaso-inhibitory preponderance becomes in varying degrees and continuity permanent.

TABLE OF 238 CASES OF COMPLETED OVARIOTOMY (163 TO 400) WITH REMARKS.

By George Granville Bantock, M.D., F.R.C.S.Ed.,
Surgeon Samaritan Free Hospital.

As an appendix to a paper on "Hyperpyrexia after Listerian Ovariotomy," read before the Royal Medical and Chirurgical Society in December, 1880, I published a table of 162 cases of completed ovariotomy. The accompanying table carries the number to 400, and it will be interesting to compare the state of the Listerian method then with what it is now. In 1881 there was only two men, as far as I know, who ventured to perform ovariotomy without a rigid observance of all the details of the Listerian method. These two men were Mr. Lawson Tait and myself, and it is a fact worthy of repetition that we were working quite independently of one another, neither, as far as I am aware, knowing what the other was doing. At that time the method in question was in full swing; the belief in it, however ill-founded subsequent experience has shown it to be, was firmly rooted in the professional, and even in the public mind, and any one who ventured to express his disbelief, and especially who dared to ignore it in practice, did so at his peril. The younger race of practitioners, and especially men fresh from the medical schools, all talked glibly of the antiseptic method, and stood incredulous at the bare idea of performing even the most simple operation without "full antiseptic precautions"—as the phrase went. Every successful operation was due to the observance of the Listerian method, every failure to some fault in its application, and the most absurd explanations of the latter were forthcoming, and gravely put forward. Much ingenuity was exhibited in this way, and the imagination was allowed free play. I shall not again go over the ground covered in my inaugural address on "Listerism" before this Society, to which no one has yet ventured a reply.

What is the state of the question now? Simply this, that, in this country at least, it is a very rare thing to see the spray in use at all. For the most part it is to be seen put to a purpose for which it was never intended by the inventor, *i.e.*, playing upon the ceiling, or against a wall, or anywhere but on the field of operation. This is at best a most illogical proceeding, and I am quite at a loss to understand the process of reasoning—if there be any—which leads to such a practice. In the Samaritan Free Hospital it has been discarded by all my colleagues with one exception. I am making no assumption when I say that this is due to the superior results which I have obtained there since I reverted to a more rational and more simple method.

Still the belief in so-called antiseptics has a firm hold on many minds, and, although the belief in the efficacy of the spray has well-nigh died out, it is not so with other details of the method. For whether it be carbolic acid, or corrosive sublimate, or boracic acid, or whatever it may be, few operators venture to perform an operation without

employing one of these agents for the hands, sponges, and instruments.

I have frequently been asked the question, "Would you open a knee-joint without using an antiseptic?" My answer has been "Yes, most certainly, if the opportunity offered," for I see no difference between the serous membrane of the knee-joint and the abdominal cavity.

I have said that I am making no assumption when I say that my results in the Samaritan Free Hospital have led to the almost complete extinction of the spray in that institution. What are these results? I confine myself to the cases of ovariotomy, and I now record it as a fact that from April, 1885, to October, 1888—a period of three years and a half—I did not lose a case in that hospital with a series of ninety cases. On the other hand, during this period the mortality under the Listerian method exceeded 12 per cent. Moreover I affirm, without fear of contradiction, that my patients recovered with less pyrexia than under the carbolic acid treatment

It is, therefore, to me a source of much gratification now, and a set-off to the obloquy and misrepresentation to which I was subjected a few years ago, that I have the reward of seeing my views triumphant. I was justified in expecting this, for it was not the result of prejudice or vain speculation, but of a rigid attention to and a careful study of observed facts that I enabled to arrive at the conclusions I reached.

I have deemed it advisable and even necessary to recur to this question once more—I hope for the last time—for I am constantly learning that there still exists a belief that I employ some so called antiseptic in my operations.

Once more then let me say that for my hands, instruments and sponges, I use plain water; that I take no precautions to sterilize it, as it is called, by boiling; that I regard water that is fit for drinking and household purposes generally as suitable for the purpose of any operation; that while the water is heated—but not necessarily boiled—I have no hesitation in cooling it down, if too hot for my hands, with cold water drawn fresh from the tap, as for instance, when washing out the peritoneum, and that I pay the greatest attention to cleanliness and see that all utensils are as clean as water can make them. I wash my hands very carefully before commencing an operation, making them as clean as soap and water and a nail brush can make them, and I frequently cleanse them during the operation. I go so far as to use the nail blade of my pocket knife for removing all matter from under my nails after washing, without adopting that refinement of absurdity which consists in previously passing the blade through the flame of a spirit lamp, and I refuse to follow the teaching of Goodell, who regards it as a dangerous practice to disturb the germs or microbes, lurking under the nails. As a covering to the wound I employ simple absorbent gauze, perfectly innocent of any germicide or foreign substance. And such is my disbelief in the hurtfulness of "germs," that, were it not for other considerations, I would leave all my wounds exposed to the air—as for example, I have sometimes done in amputation of the breast, and always do in the operation for restoring a ruptured perineum.

What, then, are the results of this method, speaking generally? They are these, viz., that while in my first hundred ovariotomies, the majority having been done under the Listerian method or a modification of it, I lost nineteen cases, in my second hundred, while I was gradually abandoning this method, the mortality fell to fourteen; in the third hundred all performed with plain water the mortality was eight, and in the fourth hundred it was only four. In what I may call the general part of gynæcological surgery my perineal operations are out of hand in a fortnight, and it is a rare thing to see a breast case otherwise than practically well in a week.

In several particulars my practice now differs materially from that of nine years ago in the general management of an ovariotomy.

(1) *Washing out the peritoneum.*[1] The first case in which I resorted to this practice was nearly five years ago, viz., on November 13th, 1884. It happened thus: On November 12th I was consulted by a married lady, æt. thirty-nine, the mother of two children (No. 268 in the table). In the course of examination and while endeavouring to push up a tumour lying in Douglas's pouch, for the purpose of determining whether it was movable and a fibroid or not (there being some fibroids in the uterus also), suddenly I felt something give way, and the tumour disappeared both from the pelvis and hypogastrium, leaving the uterus with its fibroids to be clearly made out. As soon as possible I made arrangements for abdominal section, but these could not be completed untill the following morning. In the course of the evening of the same day there was a slight rise of temperature to 99·4, with some uneasiness in the lower abdomen, but on the following morning the temperature had returned to its normal standard. As soon as the peritoneum was opened a dark-coloured fluid like thick coffee welled up. After removing the ruptured ovarian cyst I freely washed out the peritoneum with warm water, using a quart jug for the purpose, and put in a drainage tube. The patient made an uninterrupted recovery and is still in very good health. The fibroids have given her no trouble. I did not use it again till March 16, 1885, when I encountered a case in which there was active peritonitis with recent parietal and pelvic adhesions and a great deal of free fluid in the peritoneal cavity. Since that time I have resorted to it very often and with increasing frequency until it has become the rule to employ it whenever any ovarian fluid has been spilt into the peritoneum, or there is any bleeding from torn adhesions, At first I used whatever came most conveniently to hand—a pint or a quart jug, or a clean Higginson's syringe—but for a considerable period I have used Lawson Tait's apparatus, which I am sure he will forgive me for saying I believe I have improved by adding a ball free from valves to facilitate the starting of the siphon action.

A full stream of water, such as this apparatus gives, removes all clotted and fluid blood, serum, debris, of a broken-up ovarian tumour, or fibrinogen much more effectually than it is possible to do by any other means, and without any irritation of the peritoneum. It is especially useful, as has already been pointed out before this Society, in cases of ruptured colloid tumour, for the warm water rapidly dissolves out the colloid matter which in these cases is so frequently found attached to the omentum, appendices epiploicæ, etc. I have never known any evil result follow its use, but I have several times regretted that I did not resort to it. Nor am I at all particular in getting all the water away. Sometimes, as for instance in the case of large tumours, the intestines will not descend into the pelvis before

[1] I have already given Mr. Lawson Tait the credit of having introduced this practice, and have therefore though it unnecessary to repeat it in the next text.

it is time to close the abdominal wound, and a cavity filled with air would be left in the pelvis. In these cases I leave sufficient water to fill up the space to come away subsequently through the drainage tube. Again, in the case of ruptured colloid tumours, every one who has had any experience knows that the peritoneum is usually covered with a very delicate layer of capillaries, the slightest sponging of which causes serious injury and oozing. In these cases also I remove no more water than comes to the surface.

At the meeting of the Society on November 14th, 1888, I called attention to a fatal case under the care of Dr. Polaillon, in which death was attributed to the washing out of the peritoneum. This case was reported in the *Journal de Medicine de Paris*, October 28th, 1888, and in the *Bulletins et Memories de la Société Obstetricale et Gynécologique de Paris*, Seance de Novembre, 1888, and is as follows :—

"In consequence of the effusion of blood into the pelvis, Dr. Polaillon washed the peritoneum with distilled water, which was boiled and carbolised to 1 per cent., and used at a temperature of 37° (C) or 98·6 (Fahr.) by means of a glass tube, which carried the stream to the bottom of the pelvis. The washing had been continued for two or three minutes when all at once the respiration quickened, then became shallow, and finally ceased. The face became livid, but the heart continued to beat regularly. This was at a quarter-past ten o'clock. Artificial respiration was at once practised, and continued methodically. At eleven o'clock, respiration not being restored spontaneously, an incision was made for tracheotomy. A few feeble respirations followed and continued regularly for ten to fifteen minutes. The face became less livid; the pupils were half contracted; the heart beat regularly, but consciousness did not return. Advantage was taken of this improvement to close the abdominal cavity and complete the dressing, the pedicle being kept outside, secured by two pins and an elastic cord. In spite of the inhalation of pure oxygen, and various other means which need not be mentioned, respiration could not be established in a durable manner, and artificial respiration was again resorted to. An attempt to bleed from the arm yielded only a few drops of black blood. The heart beats became more and more quick, feeble and irregular, but there was no spontaneous respiration. Soon the heart beats were no longer perceptible; the face became more and more pale; some gas escaped from the anus; the pupils dilated. Within a few minutes of twelve o'clock death was incontestable.

"The administration of chloroform had lasted thirty-five minutes, and nearly forty grammes (about ten fluid drachms) of chloroform had been used. The quantity of chloroform absorbed by the patient cannot be exactly determined, but by reason of the evaporation it was certainly much less than the amount employed.

"This death has not for its only cause the action of chloroform, as some will not fail to say. In my opinion, we must also blame the washing out of the peritoneum."

Dr. Polaillon then refers to two other cases in which respiration was temporarily arrested at the moment of the injection of very warm water, but in these two cases it was re-established. In the case in question he says he had already poured two litres of warm antiseptic water into the pelvis, and as it flowed over very much tinged with blood, he poured in another which was accidentally much warmer than the preceding. The pelvis being full of water this injection extended to the upper part of the abdomen. "It was at this moment," he says, "that the respiration became arrested." He believes that it was the contact of this hot water with the diaphragm or the solar plexus which produced an impression, which, by reflex action, provoked the arrest of respiration and syncope, and he compares it with the effect of a blow on the epigastrium. He adds, "the combined action of the chloroform and the warm injection caused the death of my patient; but I am convinced that the injection was the principal cause."

When I first called attention to this case I gave it as my belief that the death was due to carbolic acid poisoning. In this view of the case I am glad to find myself supported by Professor Japp Sinclair. It would appear that the attention of the operator was taken up with attempts at restoring the respiration, and that nothing was done—at least for considerable time—in the way of removing the carbolised water from the peritoneal cavity. Hence with the continuance of the circulation, it is a fair assumption that absorption continued, though in lessening degree during all this time. That Dr. Polaillon was right in attributing the fatal result to the injection, and absolving the chloroform I am fully convinced, but I am equally convinced that he entirely overlooked the part played by the carbolic acid.

In a recent number of the *Annales de Gynécologie* (September), Dr. Perrie Delbet has published an interesting series of researches on this subject. With regard to his conclusion that, because foreign matter cannot all be removed from the peritoneum by flushing, it is best to emply an antiseptic solution, I shall only say that experience does not bear him out. His experiments tend to show that the temperature of the water within the limits of 65° to 122° (Fahr.) has no appreciable effect on the respiration or circulation, but that a low temperature by its chilling effect increases shock. He is of opinion that in Dr. Polaillon's case the carbolic acid or the anæthetic may have had the principal share in the fatal result, thus absolving the mere act of flushing, and he doubts the alleged hæmostatic action of very hot water. He points out that during the first minutes a great quantity of water is absorbed, and that when salt in the proportion of seven parts to one thousand of water is used the process becomes "a true indirect transfusion." It is probable that with water alone the same result would be obtained. Hence we can imagine that this process might be of service in lessening the shock due to loss of blood, the suggestion of which is claimed by Dr. Gill Wylie. One important fact which is brought out in Dr. Delbet's experiment is this, that after flushing the peritoneum for ten minutes with the saline solution, a poisonous fluid may be diffused over the peritoneum with impunity, provided that it be followed by another flushing with the saline water.

I have washed out the peritoneum in more than one half of the last hundred cases in the table, and I have never seen anything approaching the condition described by Dr. Polaillon. In many of these the abdomen has been completely filled. I cannot but believe that if Dr. Polaillon had used plain water instead of a weak solution of carbolic acid, he probably would not have met with such a disaster in the case in question, nor the serious symptoms he observed in two others. It is probable that a weak solution of carbolic acid might be absorbed by the peritoneum in considerable quantity, while a stronger solution, by virtue of its caustic and coagulating property, would have the effect of closing

the mouths of the lymphatics, and thus limiting the absorption. It is too late to deny the possibility of the absorption of carbolic acid by the peritoneum. There are too many observations on record to prove the fact beyond any doubt.

We know also that as in the case of corrosive sublimate or any mercurial preparation, some persons are peculiarly sensitive to its action, and that while in a large majority of cases no harm may accrue, yet now and then a case is met with in which this idiosyncrasy exists. This is the only rational way of accounting for the large number of deaths due to the use of corrosive sublimate. I protest, then, against the employment of any so-called germicide substance in flushing the peritoneum, and cannot too strongly insist on confining ourselves to plain water as at once perfectly innocuous, and thoroughly efficient. If, however, it should be any comfort to the operator's peace of mind to use *something*, let him limit himself to the use of that innocent, and in certain circumstances—as for instance, great loss of blood—possibly beneficient, substance, known under the name of common salt.

(2) *The Treatment of the Pedicle.*—More than seventeen years ago I exhibited a specimen before the Obstetrical Society of London which illustrated the changes which take place in the pedicle of an ovarian tumour—and it applies to all pedicles—after the application of the ligature (Obstet. *Trans.*, January, 1872), and the explanation I then gave of this process is now universally accepted as the correct one. But it is rare to find the credit assigned to the right person. At that time, and for several years after, the clamp was almost universally used. In the beginning of the year 1876, dissatisfied with the clamp, and on the faith of the observation just referred to, I announced my intention of exclusively employing the ligature until I had settled the question to my own satisfaction. Since the 25th of November, 1875, I have used it exclusively, and I have now the satisfaction of witnessing its almost universal adoption. (I appeal to the writings of Mr. Lawson Tait for an expression of opinion as to the beneficial results of the change.) I soon, however, found that there were difficulties in the way, for I lost my nineteenth case from the slipping of the outer edge of the pedicle—that edge which consists of two folds of peritoneum with its contained vessels. To obviate this source of danger I adopted the plan of first securing this fold by a separate ligature before transfixing for the main ligatures. This plan has never failed me, but its omission has more than once led me into disaster. It has been suggested that the object to be attained was the securing of the blood vessels. To a certain extent that is true, but that result is attained indirectly, for it has never been shown that the vessels have retracted while the folds of the peritoneum remained encircled by the ligature. Nor can it be. When the peritoneum of this part of the broad ligament is folded upon itself, as must happen in the case of a broad thin pedicle, it is remarkable with what ease one of the folds can be pulled through the loop, even when the ligature is tied as tightly as possible. It was this fact that suggested the method to me.

Then again, it was suggested that the ligature should not be tied as tight as possible in order to allow of capillary circulation through the constricting loop. This suggestion would seem to have been made in ignorance of the fact that in all cases there is more or less shrinking of the tissues embraced by the loop after the tumour has been cut away. This fact is particularly seen when uterine tissue is dealt with, and constitutes the principal objection to the use of the ligature in such cases. In a large number of cases it is sufficient to transfix the pedicle, and tie with all the force the ligature will bear, using either the double ligature, the Staffordshire knot, or the figure-of-eight knot, according to the predilection of the operator. But it very frequently happens that the pedicle is so large, so thick, and so vascular that more than the double ligature is required for the main constriction. I have put on as many as nine ligatures in such a case as this. To meet this difficulty I devised the method of first compressing the pedicle by means of a pair of powerful forceps, or even two pairs. By such means the thickness of the pedicle is reduced to one-half, or even one-third of the size it would have retained under the old method, and two loops will now be sufficient instead of the three, four or five, or more ligatures formerly required. There is this further advantage that there can be no appreciable shrinking of the tissues after the application of the ligatures, while the pedicle being divided through uncompressed tissue a knob is left outside as an additional safeguard against slipping of the pedicle. For my part, I prefer the figure-of-eight loop, but this is a matter of predilection.

(3) *Opium.*—When I began to perform ovariotomy, and for many years after, I followed the routine practice of administering some preparation of opium, either by the rectum or by subcutaneous injection. The rule was to administer the sedative as soon as the patient had recovered sufficiently from the anæsthetic to complain of pain, and I believe it remains the rule with the majority of the present day. So much are we the slaves of custom that we continue the practice simply because our great-grandfathers did it. Probably most men who give a sedative now-a-days can give no better reason for so doing than I could give five years ago.

It was about the same time that I resorted to flushing the peritoneum that I discontinued the use of opium after operation. It came about in this way. Early in the year 1884 I performed ovariotomy on an old woman, æt. fifty-eight, and to arrest the very free bleeding from the parietes I resorted to ligatures and the actual cautery. The case was a very severe one, and complicated with a chronic cough. Although she was very ill on the fourth day, yet her pulse and temperature indicated that she might last another day. She had had morphia—a quarter grain—immediately after the operation, according to the usual routine, and at intervals afterwards. I had no hope of saving her, and as she was complaining of pain at my visit I wished to spare her any avoidable suffering, and gave her a sixth of a grain of morphia subcutaneously. She was dead within ten minutes. I was horrified and said to the nurse, "We must not have this happen again. For the future give only a sixth of a grain after the operation and don't repeat it if you can avoid it"

By and by I reduced the dose to an eighth, and, satisfied with the result in several cases, I afterwards reduced it to a twelfth. It was observed that there was less sickness and less discomfort generally the next day, and the tongue was more moist. Then I said, "Now we'll leave it altogether." It was some months ere we got to the end of our experiment, but so satisfactory were the results that since the beginning of 1885 no opium has been administered after *any* operation with three exceptions. In one of those 20 minums of laudanum were administered once by the rectum, in the

second a quarter of a grain of morphia was injected into the arm, and in the third an eighth.

It is at least a curious coincidence, if not a consequence, that my mortality since that time is under 4 per cent., as may be seen by the table. Not only have the patients recovered in large numbers but they have also recovered better. Any one who has experienced the after-effects of opium as I have done, especially the distressing restlessness, will be only too ready to spare his patients such suffering. Now if there is one operation more than another which would seem to demand the administration of a sedative it is that of supravaginal hysterectomy, in which the pedicle is treated extra peritoneally with the serre-nœud or elastic ligature. In that operation the pain is undoubtedly severe, at least for a few hours But it is only necessary to encourage the patient to bear the pain as courageously as possible with the assurance that in a few hours she will be in comfort. I find no difficulty in persuading her to this, not even for the purpose of allaying restlessness, for the relief of which Dr. Greig Smith still recommends it.

It is an admitted fact that opium is a virulent poison in most cases of chronic Bright's disease, and yet although my table contains several cases where there was a strong suspicion of such disease, the patients have done well.

In a paper on "The Condition and Management of the Intestine after Abdominal Section," Mr. Malcolm pleads strongly in favour of the administration of opium after operation, on the ground that "to keep the whole intestine as quiet as possible for a time would seem to be one of the plainest indications. Opium is our best agent for this purpose. Opium . . . . quiets the action of the gut, secures as much as possible the intestinal rest which is so greatly needed, and tends to prevent those irregular, fruitless and exhausting efforts which are so exhausting at this time." While, however, he admits that "opium may undoubtedly do harm in some cases and conditions," he contends that "there is abundant evidence of its beneficent action." Now this is just the point that I contest. It is certainly of the first importance to quiet "the action of the gut" after abdominal section, especially in severe operations in which there may have been "much interference with the bowel and mesentery, and laceration of these parts in the separation of adhesions," but this is better effected by giving the intestines nothing to do for twenty four or more hours, and keeping up gentle elastic pressure, or rather support, than by giving opium and binding down the intestines by stripes of adhesive plaster applied firmly over heavy and hard dressings as he has learnt to do. It would be vain to deny that opium diminishes the peristaltic action of the intestines. But it does more, it diminishes secretion. Why does a woman who has lost control over the rectum, through complete destruction of her perineum and sphincter, so often resort to the use of opium to enable her to move about without leaving behind her unpleasant traces of her steps? It is because of this double effect. Both these effects are interferences with the normal and healthy action of the intestine, and as such are not desirable.

But I will not pursue the argument further. I will content myself with expressing the hope that surgeons will cast aside the pernicious trammels of routine practice and put the matter to the test. I can confidently assure them that if they will do so—as Mr. Lawson Tait and myself have long ago done—they will have no cause for regret. It was gratifying to me to hear one of our secretaries announcing, at a recent meeting, that he had found it answer well. I trust his example will be extensively followed.

(4) *General After-treatment:* (*a*) *Vomiting.*—When I first began to have the management of cases of ovariotomy and to perform the operation, and even for several years afterwards, I used to try to stop sickness by the administration of prussic acid and other antispasmodics, and I am sure I often did harm thereby. It is now a long time since I came to the conclusion that the best way of arresting sickness was to keep the stomach as quiet as possible by preventing anything from getting into it. This is provided for in the first instance by not allowing any food to be taken for many hours before the operation. Hence I prefer operating in the morning, the last food taken being a light supper. Sometimes, however, the stomach will be found to contain some watery mucus in quantity so small that the efforts to get rid of it by vomiting are quite ineffectual. A few ounces of hot water will generally suffice to clear out the stomach, and there is no more trouble. At others bile is excreted in large quantity and gains access to the stomach. When the bile is yellow and thus gives indications of its recent entrance into the stomach, the hot water alone will probably suffice to get rid of it at once. But when its conversion to a green colour shows that it has been long enough in the stomach to be decomposed by its acid contents something more is required. The best remedy in my experience is the administration of three or four ounces of hot water containing fifteen or twenty grains of bicarbonate of soda. It is very rare, however, that I am called upon to resort to these measures, although all my patients are anæsthetised with chloroform, which in the opinion of some is so objectionable, but which I may here state is, in my opinion, and after an experience of thirty years, the best anæsthetic we possess.

(*b*) *Thirst.*—It would appear to be still a very prevalent practice to allow patients to suck ice for the purpose of allaying thirst. I would recommend the study of the literature of Arctic exploration to any one who as any doubt on this subject. He will there find unprejudiced evidence, sufficient to convince the most obstinate, of the injurious effects of this practice. Indeed, the strongest warning is given against the slightest indulgence in it, for it is so seductive in its immediate effects. Nothing gives so much relief as rinsing the mouth with warm water. Why is it that a cup of tea is so much more lasting in its refreshing effects in hot weather than a cold drink? It is because of its warmth, and the consequent absence of reaction. It seems to me so long since I gave up the practice of giving ice that my memory does not enable me to assign a date to it. Yet the practice is still so prevalent that I very seldom come across a fresh nurse without having to give her specific instructions on this point.

Peritonitis is one of the most serious conditions we have to encounter in the after-treatment of a case of ovariotomy While it was at one time a very common condition and perhaps the most frequent cause of death, I am happy to say that several years I have had very little experience of it. In this I consider myself very fortunate, for I must confess that I have little or no faith in any kind of treatment. Lawson Tait and Greig Smith tell us that they are in the habit of meeting the first symptoms of peritonitis by the administration of a saline purgative. I have no experience of this method of treatment, and I fail to understand the *rationale* of it. Now peritonitis may arise from causes operating within the peritoneal cavity, or outside it. I need

not enumerate the various causes of the former, the chief of which has been obviated so largely by the use of the drainage tube. The latter is due to the presence of irritating matters in the digestive tract. In the former class of cases I believe we are helpless, unless we can remove the offending material from the peritoneal cavity. This can only be done by re-opening the peritoneum, and the treatment must be surgical. In the latter, however, our resource must be found in the medical art as distinguished from the surgical. Now, in my experience, one of the first, if not the first, symptom of peritonitis is vomiting. But every case of vomiting is not one of peritonitis, even when occurring several days after the operation. Nor is tympanites a sure and certain sign of peritonitis. It is particularly a sign of obstruction, whether from paralysis or mechanical obstruction of intestines from any cause. The following case illustrates what I mean. Some years ago a patient of mine was seized with sickness several days after the operation of supra-vaginal hysterectomy. The vomited matter went through the various changes until it assumed that appearance which so often indicates a fatal termination, viz., black vomit. All food had been stoped by the mouth without any benefit, and beef tea enemata had been substituted. Happening to pay a visit when the beef tea injection was due, I inquired if everything had come away, when the rectal tube was passed as a preliminary. There was undoubtedly some fæcal matter in the refuse. I had a large enema at once administered. It brought away a considerable quantity of fæcal matter, and it was not till eleven or twelve enemas were given that I was satisfied that all the accumulation had been removed. The vomiting ceased as if by magic, and did not return, and there was no further trouble. I have my own opinion as to what would have been the probable result had I given an aperient, saline or anything else, instead of the injections.

In such a condition as that indicated by Tait and Smith, I have adopted an opposite course—and I have had a considerable number of such cases—in stopping everything by the mouth, and the results have been most satisfactory. In my experience purgatives have always aggravated the condition. Greig Smith tells us that he believes "that a saline purge may be of advantage where there is fluid collecting in the pelvis." I am glad he finds comfort in the belief. Moreover he says—though I have not been able to verify the quotation—that Tait tells us that in many cases where others would drain, he purges. But that is a very different thing, and reminds me of the abortive treatment of fevers by an emetic. You cannot possibly prove your case. On the whole, then, while fully accepting the statements of Tait and Smith as statements of fact, I am not prepared to accept their interpretation of those facts, and I believe we are as far as ever from the attainment of a successful method of treating actual peritonitis.

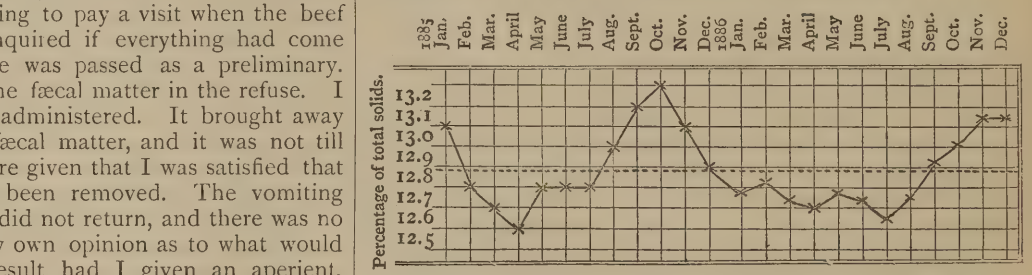
THE MILK SUPPLY AND LUNACY.

By William Ackroyd, F.I.C.,

public analyst, halifax.

Some interesting statistics of admissions to lunatic establishments for the period 1880-87 are given in the thirty-first Report of the General Board of Commissioners for Scotland. The monthly returns for these years show that there are well-marked seasonal fluctuations. Thus the average monthly number of admissions for the eight years is 1,699; and in the months of May, June, and July, the number is 628 above the average; while for the months of October, November, December, and January, the number is 462 below it. The rise and fall is gradual; the number is going up in February, March, and April, and is going down in July, August, and September. The regularity in the rise and fall is twice interrupted. Thus in the first half of the year the rise is interrupted by a fall in April, and the fall is interrupted by a rise in December.

Such variations have, I believe, been correlated with a number of other phenomena, such as atmospheric condition, temperature, barometric pressure, season, etc., and I desire in this communication to add one more to the list, viz., the seasonal variation in the quality of milk. The accuracy with which the total solids can be ascertained makes this a good number to take for the purpose, especially if it be an average each month of a vast number of analyses. The requisite data have been furnished in *The Analyst* for some years back by Dr. Vieth, the analyst for the Aylesbury Dairy Company, and I give below a curve I have plotted for the year 1885, which is based on 16,037 samples of milk analysed for this company, and a continuation of it for 1886, based on 17,269 analyses.



If we assume that mental aberration and weak milk are both alike indications of lowered vitality, then a curve like the above ought to bear an inverse relation to the *data* given at the commencement of this paper—*i.e.*, when the rate of admissions to asylums is rising, the quality of milk ought to be falling, and *vicè versa*.

The horizontal dotted line represents the average of total solids in milk for the two years covered by the curve. On comparing the results plotted in this diagram with the statistics given in the first paragraph, it will be observed that when admissions to asylums are above the average, in May, June, and July, the milk curve is below the line, and when the number is below the average, in October, November, December, and January, the milk curve is above the line. When the number is going up the curve is coming down, as in February, March, and April, and when the number is going down, in July, August, and September, the curve is rising. Further, after the first indications of a rise in the curve have been manifested, there are fluctuations which roughly correspond to the interruptions noted by the Scottish Lunacy Commissioners.

For an exact comparison, English statistics ought to have been available. I am informed, however, by the Secretary to the Commissioners in Lunacy, at Whitehall, that no record has been kept hitherto of the number of persons registered as insane, month by month, nor has it been considered worth while to do so. It is also pointed out to me that the first symptoms of insanity rarely correspond with the date at which patients are first placed in asylums, or certified to be insane; that it is, as a rule, only when an insane person becomes too troublesome or

dangerous to be any longer regarded or dealt with as sane, that their relatives or neighbours take action upon their insanity; and thus that the date or month when a patient becomes certified is very fallible evidence of the commencement of their madness, and cannot be reasoned upon as a fact of established value fit to compare with others, such as I have here introduced.

I may point out, however, that in an inquiry like this, we are dealing with averages founded upon a great number of observations, and that possible sources of error arising from the delay referred to are practically eliminated; indeed the only result we should look for would be a slight lagging of the insanity curve behind the milk curve. But apart from this consideration, I think it will be admitted from the foregoing facts, that even with the imperfect *data* at command for comparison, one is justified in concluding that the tidal fluctuations in quality of milk and tendency to madness closely correspond with each other, and that it is a subject worthy of further and more precise study.

SCARLET FEVER.

By Charles Orton.

Some time ago, while in attendance on a case of scarlet fever in an adult, my attention was called to an article in the *British Medical Journal*, by Mr. Parker, of the East London Children's Hospital, wherein he questions the wisdom of trying to escape an attack of measles or scarlet fever during childhood, when the fever may be gone through with ease and comfort; and forecasts that fevers will tend to occur in epidemics, become severe, and occur very largely among the adult population. [I wonder whether he would have applied these doctrines in years gone by to typhus.] Further on he says: "By all means isolate a house when infection breaks out; keep it there until it has exhausted itself, and adopt every known precaution in the way of disinfection afterwards." This practice he recommends, while he ventures to think that the more carefully isolation is practised, the more frequent will epidemics become. I will not venture to discuss this question; but I will give you, for what it is worth, the opinion I have formed after twenty-five years' work in Newcastle-under-Lyme upon another statement made by Mr. Parker—that "it is a matter of experience that the exanthemata run a severer course in adults than in children." So far as scarlet fever is concerned, I am of an opposite opinion. The oldest person I ever saw with scarlet fever was aged twenty-seven, and that individual was myself. It was of a very mild description, unattended with any kidney trouble. The late Dr. Alfred Cotterill, then a student, contracted the fever at the same time, and from the same case, which was one of a malignant and fatal character. Dr. Cotterill had some slight rheumatic fever following; but though worse than I, was never, I believe, seriously ill. Here we have an example of a malignant case begetting others of a milder form, but in older individuals. On the other hand, I have seen very mild cases indeed beget others of a malignant type. Mr. Parker says the malignant forms ought to be most carefully isolated. Certainly, and so ought to be the milder forms; for however mild a case of scarlet fever may appear, depend upon it, you are treading on very dangerous and treacherous ground.

Now we will just glance at the tables of mortality for the twenty-five years. There are 176 deaths. In the first ten years of my practice the deaths numbered 129; in the first fifteen years following, only fifty-three, and during the last two of these fifteen years there has not been a single death in Newcastle from scarlet fever. I cannot help thinking that the improved sanitary condition of the town generally, the improved drainage of the streets, the better hygienic state of nearly all dwellings, has had much to do in lessening the mortality of this once fearful scourge.

With regard to the severity of scarlet fever in the adult, well, I have only treated one case within the last ten years, and that was a very simple uncomplicated case, and I have never seen a severe case in an adult. Looking again at my tables of mortality, we only find two deaths in the whole twenty-five years of individuals over fifteen—viz., one at nineteen in 1871, and one at twenty-one in 1876. How different is the record as you approach the first years of life. Of the total 176, 174 are under fifteen, 161 are under ten, and 117 are under five. It is interesting to notice the different death-rate between the first and second year of life. Under one year there are only six deaths; between one and two there are thirty-two deaths. My advice is to isolate every case, however mild, most rigidly; disinfect clothes, rooms, and the patients' body; burn old books and rags, in fact, everything of little or no value. Take care of the infants of the present, and let the adults of the future take care of themselves.

Ages	Under 1 year	Over 1 & 2	Over 2 & 3	Over 3 & 4	Over 4 & 5	Over 5 & 6	Under 6 & 7	Under 7 & 8	Under 8 & 9	Under 9 & 10	Between 10 & 15
	6	32	27	25	27	18	12	6	4	4	13

Between 15 and 20, 1 (at 19), and 1 at 21.

Under 5 years, 117; over 5 and under 10, 44; under 10, 161; over 10 and under 15, 13; under 15, 174; over 15 and under 20, 170; and one solitary death at the age of 21. Total, 176.

From 1st January, 1864, to 1st May, 1873, there occurred 129 deaths—one at the age of 19 in 1871. From 1st May, 1873, to 1st January, 1889, there occurred 53 deaths, one at the age of 21 in 1876.

ACUPUNCTURE.

By Charles R. Illingworth, M.D., M.R.C.S.,

Medical Officer, Rishton District of Blackburn Union.

The relief of pain by acupuncture is so pronounced and remarkable that the cases suitable for the adoption of this ancient remedy deserve more than a passing notice. As I have the utmost confidence in its power to relieve the vast majority of those cases which are generally treated by morphia hypodermically, I have thought that a short account of twelve or fifteen cases, taken as they occurred in my practice, may not be without interest to your readers. My hypodermic morphia is now dust-covered on a back shelf; whilst my acupuncture needles are plunged into some antiseptic ointment, fully a score of times a month, in preparation for the relief of muscular, rheumatic, and other pains, whether from bruises, twists, sprains, or any other accident to which the muscular system is subject. I use those which are one and a half inches in length.

1. J. R——, a collier, æt. twenty-one, complains of pain under the left twelfth rib anteriorly, which catches the breath and is aggravated on moving the body. Pulse 108; slightly feverish. Diagnosis, pleurodynia with catarrh. An acupuncture needle plunged in on to the rib at the painful spot removed the pain at once. Suitable medicine prescribed for the cold.

2. J. M——, an old lady, fell down stairs and bruised the back of the body fearfully. In three days I was sent for and found her quite unable to move without the most intense pain at one or two badly bruised places. A needle was thrust right through the bruised tissues down to the ribs, in a slanting direction, at the painful parts, with complete relief. Next day the pains affected other bruised parts, and the same means were adopted with equal effect. In five days she was able to walk down, and remained free from further attacks.

3. Mrs. W——, after kneeling to clean the floor for two hours consecutively, was seized with great pain in the thigh. After passing a sleepless night she sent for me. I found the flesh on the anterior aspect of the thigh hard and painful to the touch. I passed a needle right through the most painful parts in two places, and immediate relief was obtained. The pains did not return.

4. In three cases of loss of some power in the hand, and peculiar pains on the outer and anterior aspect of the forearm, I have found tenderness on the outer aspect of the upper arm, immediately above the external condyle, and in the vicinity of the musculo-spiral nerve; and I have effected rapid cures by inserting three or four needles down to the bone for a few minutes.

5. A little boy in the coalpit had his arm violently wrenched at the shoulder. He had no sleep, and no rest from pain at one point in the shoulder for forty-eight hours. I found the deltoid muscle hardened, and, as it were, "in a knot" at one point. A needle plunged into this gave instant relief, and the pain never returned.

6. Sciatica. In these cases all that is needed is to hit the nerve with one or two needles, and the pain at once leaves.

7. T. H——, æt. thirty-three. This patient had had lumbago for a month. He couldn't turn in bed, or stoop the least bit without excruciating pain. I plunged a needle into each side of the back, deeply into the erector spinæ. The cure was instantaneous.

8. J. B——, æt. fifty, fell, and in saving himself twisted his back considerably. He complained of pain a few days afterwards in the mid-lumbar region. I plunged a needle into the erector spinæ at the tender point, and the cure was instantaneous.

9. J. W——, a printer, fell on the arm of a chair and bruised his ribs. He came to me on the fourth or fifth day afterwards with great pain over the twelfth rib on the right side. One needle gave him relief at once.

10. J. B——, æt. fifty, overlooker at a mill, sprained his back with lifting a heavy weight five hours before. I was summoned, and found him lying on his face unable to move, and suffering intense pain. In the mid-dorsal region, at one point, there was great tenderness on palpation. A needle was thrust into the substance of the erector spinæ and other tissues at the point of tenderness, and the pain left him at once. He got up and went about his work.

Acupuncture cures by relieving tension. There is stagnation of blood, or slow circulation. Local venesection is performed into the tissues, with the effect of unloading tightly-packed vessels and consequent relief. In sciatica and other inflammatory nerve affections, there is effusion into the nerve-sheath at certain points; the needle punctures the distended sheath, and relieves tension by evacuating the effusion.

IS LIFE WORTH LIVING?

By Alfred J. H. Crespi, Wimborne.

Perhaps no stranger text could be chosen for a paper by a medical man, whose mission is to lengthen life. If life is not worth having, why then of all men he, whose aim is to prolong it, must be most miserable. But would many people unhesitatingly admit without reflection that life was worth living. Only think of the bitter competition to which most men are subjected: the petty enmities, the disappointments, the unrealised hopes, the warfare within and without, and then can you be surprised if the answer is given with some hesitation. Ask a musician, for instance, if the "Messiah," the "Elijah," or the "Creation" is beautiful, and he answers "yes," wondering what you mean. Ask him if life gives him unmixed satisfaction and pleasure, and he almost as certainly replies, "Well, no." No question is easier to put, none more difficult to answer, although most men have a conviction that life is a privilege. Nevertheless, in certain moods no passages perplex us more than those in which the Master implies that life *is* a privilege and a blessing. When we think of the misery around us—the blighted hopes, the blasted reputations, the sin—it is a grievous trial of faith to admit unhesitatingly that the mere act of living is to nearly all men a pleasure. "If," says Sir John Lubbock, "we do our best; if we do not magnify trifling troubles; if we resolutely look, I do not say at the bright side of things, but at things as they really are; if we avail ourselves of the manifold blessings which surround us, we cannot but feel that life is indeed a glorious inheritance." Exactly so, but how many *ifs* are needed before we reach that happy goal.

Schopenhauer held that all men were hopelessly wretched, and he would have a goodly army of supporters. What do most of us yearn for?—a future whose joys will be purer and less alloyed. We do not mean a future life, which none would care for were it only a repetition of the present, but future years, with the conditions of existence more congenial and ennobling. So it ever is with men—the future rather than the present. The schoolboy longs for the greater freedom and more abundant opportunities of active competition with his seniors: the young man commencing life still looks ahead; the veteran closing his career, if he remains fit for work, sighs for something he has not yet found. Life, as most men know it, is too much made up of disappointment and sorrow to be thoroughly enjoyed, and the future still beckons on and deceives. Yet, however great his occasional despondency, the Christian cannot help being consoled by the solemn words of the Master: "It had been better for him had he not been born," undoubtedly implying that, in the vast preponderance of cases, life is a priceless privilege, and that not to have had it would be a distinct loss. Perhaps after all no words rightly understood give greater consolation; and so we have found, when we have despaired of ourselves and our fellows; and when we have been ready, in the language of Dr. Samuel Wilks, to join in the universal refrain of humanity—a refrain implying trouble, anxiety, and unceasing toil—the sweet music of those words ringing in our ears has renewed our courage. Nevertheless, it cannot be denied that the conditions of existence are often disheartening and sorrowful: the toil of the underpaid town

labourer, amid surroundings depressing to a degree, scarcely to be grasped by the more fortunate, has, at first glance, no silver lining to its dark clouds. It is some consolation to think that there may be truth in the reflection of Mr. W. H. Mallock, that those who have never known greater freedom and more abundant opportunities are not necessarily unhappy, and may, after all, find solid enjoyment in life. This thought may nevertheless be pushed too far, for, if accepted without qualification, it seems to convey that increase of knowledge and opportunity does not add to enjoyment. Does not the Master warn us that the greater the talents, the more must be accomplished? Perhaps one of the compensations of the obscure toiler, is that he need not concern himself so intensely with the future, and with the condition of vast classes. He is more immediately occupied with what surrounds him—his own trials, duties, and aspirations, and those of his family and companions. Culture and knowledge enlarge the sympathies and carry the thoughts over vast regions and many years, but though the horizon is widened, enjoyment may not always be so, unless greater knowledge is accompanied by greater sympathy and more reverent faith. A friend of ours, a brilliant surgeon of national reputation, tells us that when hastily summoned to the great hospital, of which he is so distinguished an ornament, to perform some terrible operation, he cannot, when the sufferer is young and vigorous, keep his thoughts from painfully dwelling on the blighted future before the victim—maimed in life's early morning on the threshold of existence, and he adds that he half envies the indifference of the nurses and the students, who seldom seem to look beneath the surface. We once remember seeing a very commonplace artisan, not at all interesting in appearance and manner, who had had his right hand taken off by that beautiful but terrible instrument, a circular saw: the injured part was skilfully and promptly attended to, and the poor fellow was roughly grateful, but the first words he uttered, when he awoke to a consciousness of the calamity that had befallen him, were, "Done for." The shock of the accident, the torture of the wound were forgotten, and he only thought of the crippled state in which he would pass the remainder of his days. He could not have conveyed his thoughts in elegant language, but perhaps that sturdy Birmingham mechanic felt as acutely the loss of independence, and the hopeless struggle awaiting him for the necessaries of life as a man far more highly trained could have done.

It is some comfort to hope that the poor and neglected do not feel their sufferings as overpoweringly as we should were we placed, without losing our higher aspirations, in similar circumstances. But is it certain that some among them do not feel their misery more intensely than is generally supposed? "Repose," says Dr. Wilks, "is the aspiration of mankind;" and he is right; not sensual qualification, but repose, freedom from anxiety, a mind at peace with itself and the world; but how seldom does repose in this sense sanctify even the greatest and purest lives?

The most painful feature of modern life is the growing uncertainty among the thinking classes as to the destinies of mankind here and hereafter—an uncertainty finding most frequent expression in religious questioning. "Nothing particular is true," his manner said, "and all action is a degrading *pis aller*. Get through the day somehow, with as little harm to yourself and other people as may be; do your duty, if you like it, but for Heaven's sake don't cant about it to other people." In this brief description of Edward Langham's moral attitude, Mrs. Humphry Ward, in "Robert Elsmere," has faithfully rendered the characteristic traits of many modern men of culture. Tens of thousands of lives would become beautiful and useful could they with implicit confidence accept the Divinity of Christ, and believe that man was slowly but surely fighting his way to a higher and happier level. "And meanwhile, half the tragedy of our time lies in the perpetual clashing of two estimates of life—the estimate which is the offspring of the scientific spirit, and which is ever making the visible world fairer and more desirable to mortal eyes; and the estimate of St. Augustine." So says a distinguished living writer. We take exception to the passage. Truth is no doubt one and indivisible, but none the less is it many-sided, and it may be thoroughly examined and distinctly seen by many different minds approaching it from different directions, who, in their several ways, try to live in accordance with it, humbly seeking to do God's will, as they perceive and understand that will. On no other theory could we reconcile the different shades of belief among Christians, all intent, as we venture to hope, on reaching a higher level, and to subject their will to Christ's, and yet holding one another's minor differences in abhorrence, and fixing their thoughts rather on trifling diversities of opinion than on the great, soul inspiring agreements. Not that doubt is confined to our age and country; in many of the sublimest passages of Holy Writ traces are clearly discernible of the same foreboding. "Vanity of vanities," saith the preacher, "all is vanity;" and Job seemed as much distracted by uncertainty as any guesser after truth of our own day. Modern speculations have increased and are increasing the number of doubters, and over many a profound intellect and noble life lies the deep shadow, not of vice, self-indulgence, and passion, but of honest, painful doubt that nothing can solve. Faith is the gift of God, but how few have it in conjunction with a calm, perfectly trained intellect? One of the most accomplished and highly cultured Baptist ministers we ever knew, a man distinguished for scholarship and his ripe, well-balanced judgment, was one day discussing these problems with us. "Now that modern speculations," observed our friend, "are undermining the faith of thousands, and throwing doubt on the cherished beliefs of the past, one thing and one only saves me from utter despair—the certainty that all is working together for good, and that the purposes of God are well established from everlasting to everlasting." But to grasp *this certainty* is *the* difficulty which perplexes so many minds. Is all really working for man's higher good? does God jealously watch over his creatures? The speculations which have assigned to man an antiquity of tens of thousands, perhaps of millions of years, and given the universe an immensity undreamt of till the present century, seem to have deposed this earth and its human tenants from the proud position once occupied by them. To admit that man has existed through incalculable ages, and that the earth is of no more consequence in the universe than a grain of sand on the sea shore compared with the vastness of the universe, can hardly fail to have a depressing influence. We do not admit that the antiquity of man is established beyond question, nor are we convinced that space is peopled to its remotest confines. But were it only possible to the finite mind of man to grasp what is implied by omnipotence, omnipresence, and eternity, it might be conceivable that man had existed and struggled for millions rather than thousands of years, and was one only out of billions of creatures demanding

and receiving the untiring and loving care of the Most High, and yet as well guarded, as tenderly loved as though the human species was of yesterday, and this tiny globe the only inhabited one in space.

Mrs. Humphry Ward, in that remarkable but most melancholy work, "Robert Elsmere," which is being discussed by so many readers, has successfully given in Edward Langham and Henry Grey typical, though totally diverse specimens of the thoughtful, profound, and doubting characters met with in the literary and academical society of the day—men who, though widely diverging the one from the other, long for knowledge and certainty, and are as far removed from the vulgar sceptic and coarse scoffer as one human being can well be unlike another, but who none the less are perplexed and borne down by the problems of existence and religious doubts. "Mother," asks the delicate, large eyed child, Edward Langham, "how is it I dislike the things I dislike so much more than I like the things I like?" After that precocious question, the wasted and melancholy years of a blighted life seem the only possible answer to one "who never had a period in his life, when he was more struck by the difficulty of being morally strong than by the difficulty of being intellectually clear." "Light, light" is the longing of many, who, could they have it, would be earnest, and who would live with a nobler purpose. However little in our nineteenth century wisdom we reverence the saints of the mediæval Church, in one respect they were immeasurably superior to us—in their unquestioning deep-seated belief in the wise purposes and constant presence of God. The recent death of Father Damien has once more drawn attention to the unwavering faith and devotion to duty which sometimes distinguish modern Catholic priests, not less than they did their predecessors in the ages of faith. The life which has only just ended in disease and suffering could not, in one sense, have been happy, although who can doubt that the satisfaction the Belgian hero felt in doing his duty invested him with a sense of the living presence of God, which made life, instead of a slow martyrdom, one of surpassing joy. Millions of votaries of pleasure, who have hardly once denied themselves a gratification, and have perhaps never done a kindly action that involved some self-sacrifice on their part, paused when they heard of the death of the Belgian priest, and felt that it would be well indeed for them could they have borne his cross and worn his crown.

The great requisite for an earnest and successful career in the ministry of the Christian Church is *conviction.* No preacher can pour forth his soul in fervent prayer, and in undimmed aspirations for a higher life unless doubt is banished from his mind. Let the intellect become the prey of uncertainty; let the preacher fancy that all is dark within and without, that he has not realities to deal with, but speculations only, and that the New Testament records are more or less doubtful narratives of uncertain authenticity, and his usefulness is at an end, and he must fix his thoughts on all that is gloomy and awful.

"Happy, in this world, where men sit and hear each other groan!! His friend's confidence only made Langham as melancholy as Job. What was it based on? In the first place on Christianity, on the passionate acceptance of an exquisite fairy tale, said the dreaming spectator to himself, which at the first honest challenge of the critical sense withers in our grasp. That challenge Elsmere has never given it, and in all probability never will."

Were it true that Christianity was only a beautiful fairy tale, it would be a thousand fold better to accept it and take our stand among the millions whom it has sustained in lives of self-sacrifice, and whose death beds it has sanctified, than to give it up, falling into the ranks of melancholy doubters for whom life is a weary pilgrimage, and in whose hearts the sorrows and hopes of their suffering fellows find no sympathetic response. Talk of the enthusiasm of humanity, what is it unless sustained by the consuming love of Christ? Who can preach if his message is uncertain, and win the battle if he beat the air. "The Ritualist may glory in the discomfiture of an Erastian Bishop; what Christian dare parade ten years of love to God and man," but who except a Christian would devote himself to the ungrudging service of mankind.

In earnestness of purpose Abbey Gratry set the doubting Christians of our day a splendid example. "One thing astonishes me," he wrote, "it is to see Christians despairing of the world, and of its progress on the way to justice." He remained to the latest hour an enthusiast. When young he had a dream: before him life was stretched, and looking down it he saw love, honour and fame: suddenly the vision faded away, and he found himself alone: then real religion and the peace of God revealed themselves to him, and filled the void in his existence. The minister of religion ought to be the happiest and most cheerful of mortals—always hopeful, always loving: the first to promote great reforms, to widen, not to narrow; thinking the best of all men, glad if haply he entertains an angel unawares. What kind of spirit is it that sees and believes the worst, and looks on nine-tenths of professing Christians as aliens and foes. An anecdote which has often been related, though we do not know on what authority, is one of the saddest we have ever heard. It is said that after Bishop Heber's consecration to the See of Calcutta it fell to Archbishop Manners Sutton—of unhappy memory—to make a valedictory speech in the course of the luncheon at Lambeth, which followed the ceremony. "I have very little advice to give you as to your future career," he said to the youthful prelate, "but all that experience has given me I hand on to you. Place before your eyes two precepts, and two only: one is, preach the Gospel; and the other is, *put down enthusiasm.*" A minister of religion to talk in this cold and heartless fashion—to advise his brother Bishop to preach the Gospel without enthusiasm." *There* is the key to the scepticism of our days. A shudder comes over us, and we turn with deepened veneration to the ardour of St. Francis of Assisi, and of St. Francis Xavier, and think of that great preacher of our day, Fra Agostino di Montefeltro, borne by tender hands to the pulpit, which he was too ill to reach unaided; and in the greater zeal of the Catholic over the Anglican, we see a proof that Christianity is something broader and nobler than formulas and rituals, something deep down in the very heart of man. What marvellous faith Gratry had. He once exclaimed that if only twelve men were absolutely bent on doing God's will, and ready to proclaim it even unto death, they would usher in a new epoch in the world's history. And yet he loved the world intensely, not for its pleasures, pomps, and vanities, but for the sake of its Divine Master. He had an intellect that would bear comparison with that of most leaders and masters of mankind, and he was satisfied with Christianity, and in being satisfied found that peace, which Mrs. Ward describes Edward Langham as failing to secure, because he refused to believe and accept. Half the value of a doctor's

ministrations is lost if he has not cheerful resignation and lively faith; he shows to most advantage when he is a messenger of glad tidings. We know nothing more life-like than the brief sentence in which the author of "Robert Elsmere" embodies the cause of Langham's misery: his refusal to be satisfied, his stubborn determination not to allow his intellect to acquiesce in the truths of the Gospel. "He imagines he has satisfied his intellect," Langham remarks of Elsmere, when the latter at the commencement of his ministry believes and rejoices to believe, "and he has never so much as exerted it." In other words, Langham demanded proofs which, in the very nature of things, can never be forthcoming. Mathematical proof cannot be looked for in matters concerning the emotions. Do we love a man and judge him to be upright, noble, and generous as the result of weighing evidence? Do we not *feel* that he is good and pure? In like manner the strongest evidence that Christ was Divine, and really came from God, will be found in the reverent conviction that no mere man could accomplish what he did, and so completely captivate the hearts and lives of millions. Faith has its seat in the heart rather than in the intellect; it springs from a consuming love of Christ, not from a cold, critical inquiry into the evidences of Christianity, though the more carefully and thoroughly those evidences are examined the deeper must be the conviction in most minds that they are unassailable. "Savonarola," says Castelar, "would, under different circumstances, undoubtedly have been a good husband, a tender father; a man unknown to history, utterly powerless to print upon the sands of time and upon the human soul the deep traces which he has left; but misfortune came to visit him, to crush his heart, and to impart that marked melancholy which characterises a soul in grief; and the grief which circled his brows with a crown of thorns was also that which wreathed them with the splendour of immortality. His hopes were centred in the woman he loved; his life was set upon the possession of her, and when her family finally rejected him, partly on account of his profession, partly on account of his person, he believed that it was death that had come upon him, when in truth it was immortality."

The uncertainty attending modern speculations, when separated from the affections and the heart, cast a shadow over the future, which deprives many a death bed of its peace. It has been beautifully said that truth may be evolved from conflict, but never from confusion, and confusion is the frame of mind in which many modern thinkers pass their whole careers: without confidence in any creed, accepting nothing, merely giving a cold formal assent to certain general truths; they may have strength of will, but it lacks a worthy object to direct it; life is wasted, years glide swiftly by, and the bright hopes of youth fade away never to return.

"He felt that quite indisputably life would have been better worthy living if, like Robert Elsmere, he could have taken a passionate interest in rare moths or common ploughboys; but nature having denied him the possibility, there was small use in grumbling."

Some worthy object in life is what most men need, and one of the chief glories of Christianity is that it gives an object that taxes the most gifted, but is not beyond the grasp of the most ignorant and degraded. At best life is so short; so much has to be accomplished, while we have so little knowledge to sustain us. Few are those who, when they have struggled through life, and the end is fast approaching, wish to be young again. Most people dread to die; nearly all would prolong existence if they could: but to go over the same disappointments and griefs—no! Terrible to pass for ever from the bright sunshine, the birds' merry songs, the beauties of nature, the ceaseless progress of humanity, and to go forth alone into the darkness, silence and loneliness of the grave; that moment tries the strongest faith. The profoundest believer in the wisdom and tenderness of God, whose life has been less stained than usual by evil passion and self seeking, can hardly help a shudder as he thinks of the other world. He may be certain that all is for the best, that progress is eternal, and that out of evil good will infallibly come; but when death hovers over him he feels it to be awful, and yet, according to our experience—a sufficiently large and varied one—there is seldom any wish to re-enter the battle. The exquisite words of Lady Nairne, written in her seventy-sixth year, strike a respondent chord in most thoughtful hearts:

> "Would you be young again? So would not I;
> One tear to memory given, onward I'd hie;
> Life's dark flood forded o'er, all but at rest on shore:
> Say, would you plunge once more, with home so nigh?"

If in the supreme moment of his career the Christian is filled with doubt, how much more despairing is the death struggle of the man who has been drifting hither and thither without goal and without rudder?

There is something beautifully quaint in the dying words of the poor old Scotch woman, recorded by Dr. Boyd. The storm was beating furiously, the rain descending in torrents, and as she listened she calmly exclaimed, "What a fearful night for me to be flying through the air;" a composure that would do honour to a stoic, and might be envied by any Christian minister. Death cannot be avoided, and physical suffering must be heroically faced in the spirit of that German Emperor whose patient endurance has invested his memory with a thousandfold greater glory than that which adorns it as the victor in a hundred battles. The great thing in passing through life, however, is to combine faith with reason, and enjoyment with self-sacrifice. To believe, as the child believes a fairy tale, cannot satisfy the longing, reasoning soul of man; to demand proof, which cannot be vouchsafed, is to push the province of the intellect too far; to fly from the world is as reprehensible as to live for it. Life is real and earnest, but it ought to be full of joy. Was this beautiful world intended to be a sealed book? Are the treasures of art and literature, and song and architecture to be put away from the Christian's thoughts? We know a pious man, a physician, a gold medalist in classics, who lives only to study his Bible. What a melancholy contrast to Robert Hall mastering Italian just before his death, when racked with bodily anguish, to be the better able to enter into the spirit of Macaulay's criticism of Dante. When one day our friend was asked if he had read a remarkable work, which was the common talk of everyone, he answered severely that he only needed his Bible, and read nothing else. Splendid faith! some would exclaim. Ah, no! morbid asceticism, not less reprehensible than that of the man who flies from the world, and lives a life of self-concentration. The sympathies are narrowed by such a misconception of religion, the joys of life vanish, and the capacity to preach and teach is undermined. We heard not long ago with sorrow, but no surprise, that our friend was ill, and confined to his couch a helpless, suffering invalid in the full vigour of manhood. He would have used the language of

Mrs. Humphry Ward. "How could it be lawful for the Christian to spend the few short years of the earthly combat in any pursuit, however noble and exquisite, which merely aimed at the gratification of the senses, and implied in the pursuer the emphasising rather than the surrender of self. . . . . So for a short week or two Catherine Leyburn did her best to be young, and climbed the mountain grass, or forded the mountain streams with the energy and the grace of perfect health, trembling afterwards at night, as she knelt by her window, to think how much sheer pleasure the day had contained. Her life had always had the tension of a bent bow. . . . . And in a hundred other ways the relations of Mrs. Elsmere—Robert Elsmere's mother—with the poor of the parish often made Catherine miserable. She herself had the most angelic pity and tenderness for sorrows and sinners, but sin was sin to her, and when she saw Mrs. Elsmere more than half attracted by the stronger vices, and in many cases more inclined to laugh with what was human in them than to weep over what was vile, Robert's wife would go away and wrestle with herself that she might be betrayed into nothing harsh towards Robert's mother." There is no need to pass life in the absorbing pursuit of pleasure; but pleasure can be combined with duty, and life may in consequence be made a still better discipline.

The death scene of Mr. Leyburn is drawn with great beauty. After years of asceticism, as complete as that of any Franciscan or Cistercian monk, though wearing a different aspect, the end came to a life spent in God's service, and in brooding over the most subtle problems of religion. "Catherine," exclaimed the dying clergyman, "life is harder, the narrow way narrower than ever: I die;" and memory caught still the piteous, long-drawn breath by which the voice was broken "in much, much perplexity about many things. You have a clear mind, an iron will. Strengthen the others. Bring them safe to the day of account." "Yes," she answered, "Father, with God's help; oh! with God's help;" and from that day, denying herself, turning life into a veritable martydom, a perpetual repression of self, she lived on until she "knew of no supreme right but the right of God to the obedience of man." None can deny the beauty of this grand portrait of a stern, resolute, devoted woman, though many may doubt the need for that anguish and that uncompromising self-repression. "She had thought and prayed as girl and woman; she had often wrestled with despondency or grief, or some of those subtle spiritual temptations which were all which her pure faith had known, till the inner light had dawned again, and the humble, enraptured soul could almost have traced amid the shadows of that dappled moorland world between her and the clouds the white stoles and sleeping wings of ministering angels."

Religion should do still another thing: it should teach tolerance, universal compassion. In the worst of men the traces of the divine nature, obscured by sin and earthly passion, should still be distinctly perceived, and then the words of Catherine Leyburn, poured from her full heart, could never be uttered: "My father would have shrunk from him with horror; an alien from the household of faith, an enemy to the cross of Christ." How hard it is to most people to enter into the spirit of the Master! Surely no one ever had an infinitesimal portion of the loathing of iniquity which He had, and yet when the woman taken in the commission of grievous sin was brought to Him for condemnation, He did not condemn, though the Gospel narrative leaves us in no doubt that the guilty creature left his presence a thousandfold more impressed by his gentle rebuke than she would have been by the best meant homily on duty. The man who has drunk deep of the wells of truth should come in and out from the worst haunts of vice without the smallest sacrifice of dignity and purity. Lytton, in "Kenelm Chillingly," represents that eccentric hero as comporting himself more in the Master's spirit than did Catherine Leyburn in talking over the darker traits of Edward Langham's character, and there is something exquisitely touching in Kenelm Chillingly's reply to the fallen girl who seized his arm in the street. "Are you kind to-night," she inquired, in a husky, hard voice. "Kind," replied the melancholy Cambridge scholar, in mournful tones and with softened eyes; "kind, alas! my poor sister mortal, if pity be kindness, who can see you and not be kind."

The mysticism and philosophy of the child of eight who had asked his mother whether she was not sometimes overpowered by the sense of her own identity, had developed into something practical and human. If religion is only to make us unhappy, could the religious man truthfully answer in the affirmative the solemn, heartstirring question: "Is life worth living?" We are astonished how few people are able to combine pleasure with self-restraint, love of others with love of God; to be in the world, loving it intensely and revelling in it, but yet not of the world, and getting good from all things not absolutely bad. The old melancholy legend that no smile ever irradiated the Master's face strikes some people as indescribably beautiful, though to us it is depressing. What! no smile on the lineaments of Him who graced the marriage feast of Cana, extended the hand of love to the Magdalen, and sternly reproved the disciples who would have kept the little children away? Equally foreign must have been maudlin sentimentality and cruel indifference—the sentimentality which finds expression in empty words, in cant; the cruel indifference of the heartless sceptic who has his own enjoyment, and cares not a jot for anyone else. "By and by, however, as the rector penetrated more deeply into the situation, he found his indignation transferring itself more and more from the man to his Master. It became clear to him that in some respects Henslowe suited the Squire admirably. It became also clear to him that the Squire had taken pains for years to let it be known that he cared not one rap for any human being on his estate in any other capacity than as a rent payer or wage receiver. What! live for thirty years in that great house, and never care whether your tenants and labourers lived like pigs or like men, whether the old people died of damp, or the children of diphtheria, which you might have prevented. Robert Elsmere's brow grew dark over it. . . . The only constant defence which the poor have against such physical conditions as those which prevailed at Mile End is apathy." But beneath that apathy, as it seems, there is often to be found a depth of faith and a resignation which the proudest might envy.

Patience under suffering is not, thank Heaven, confined to the high born and powerful. The lowly peasant often displays it in great perfection, and were he a peer or a statesman the world would ring with his praise. A few months ago we saw for the last time a humble Dorset labourer, not the coarse monster which the Dorset peasant is often represented to be, but a gentleman in the loftiest sense—refined, courteous, and considerate. He was dying of cancer, and his wife, a tall, fine-looking, heroic woman, who expressed

herself admirably, and with a precision which few ladies could approach, was talking over the family circumstances. Of course she and her husband were poor, farm labourers always are that, but there was no repining, and they bore their lot with fortitude and unshaken trust in God. It is one thing to die in a handsome bedroom, with skilful nurses and attached physicians at hand, and the luxuries and conveniences of modern life at command; another to pass away in a mean draughty cottage, friendless and alone, with three shillings and sixpence a week to provide for all the household wants. "Ah," she said, "if the farmers would only have a little consideration, and do their best to provide work, but then we know that they have been having bad times, and perhaps it is not their fault." When her excellent husband died, she showed just the same heroism—sorrowful, but not cast down, rejoicing in the sure promises of God. Many of the poor are bad, degraded and brutal, but very far from all, and in proportion to their numbers perhaps as many heroes are to be found among peasants and artizans as among the high born and powerful. A year ago we were visiting another poor labourer, dying of consumption in the prime of life, a noble looking man with a grand, refined, expressive countenance, and a remarkable dignity of manner, He and his wife and two children had only five shillings a week; but not a word of complaint fell from his lips, though he had a deep-consuming sorrow—the dread that as soon as he was dead his wife and children would be compelled to give up the little cottage, and so lose the potatoes and other vegetables which, earlier in the year, he had still been strong enough to plant. The steward was hard, and no time, the dying man feared, would be lost in getting rid of his wife and family. We promised to use our influence with the nobleman who owned the village, and before us there lies his promise that every kindness and consideration should be extended to the survivors. Death hanging over the bed, and the thoughts fixed on potatoes and vegetables, and a mean cottage in which a wealthy man would hardly keep his horses! Is this heroism, unselfishness? Yes; his own penury and sufferings were forgotten, and his thoughts turned in tender solitude to those dearer than life . to know that his loved ones would be spared the torture of ejectment, and not be deprived of the food which he had toiled to provide—that satisfied his simple wants, and soothed his dying hour. We do not think that the rich can without a very great effort enter into the sorrows of the poor; nay, we will go further, we do not believe that, with rare exceptions, they have the necessary sympathy to come out of themselves and understand the feelings of their less fortunate, but not necessarily less deserving, brethren; and yet we venture to say, with full conviction, that if a person has the necessary qualities of mind and manner, if he will descend from his lofty pedestal of pride and self-importance, and strive to know the poor, he will find the study deeply interesting, and his faith in God and man will be strengthened and purified. The poor receive little kindness; though sometimes touchingly grateful for small attentions, and they respond as the rich never do.

"Robert Elsmere" ends gloomily: the hard-hearted Squire dies miserably; Edward Langham fritters away his days; while the hero, who does not impress us so favourably as he has Mr. Gladstone, as a splendid specimen of the highest culture and refinement of Oxford, but rather seems a warm-hearted but weak-brained enthusiast, little likely to get a fellowship, and to captivate the intellect of the first men of that ancient seat of learning, at first finds happiness in the duties of his country parish. The Squire never rests till he destroys his faith, and undermines his belief in the Christ of history. Robert Elsmere, however, does not become an atheist like his preceptor, but flies off and founds in a back street at the East End a new sect, which we are assured solved all the difficulties attendant on life, and answered conclusively in the affirmative the solemn question —"Is life worth living?" But, alas! the unstable apostle of the new creed, feeble physically if not intellectually, soon goes into a decline, and after destroying his wife's happiness and peace of mind, and not apparently doing much good in any way, leaves England to die under the bright sun of northern Africa: altogether an unsatisfactory life, and a miserable ending to it, more likely to be a warning than an example.

A young clergyman has just said to us that no wonder medical men are commonly sceptics, for they see so much of the evil side of human nature, and the lessons of the out-patient room and the operating theatre cannot but be bad. We deny the truth of both allegations, and we think that the more heartily the doctor believes in the grandeur of life and in the blessedness of living the more likely is he to discharge his glorious mission as a Christian and a gentleman.

Life to be happy must be earnest, trustful and believing: there must be a constant striving for a higher level, inspired by the conviction that such a struggle will be successful, and that He who watches over all is a real, living, omnipresent, omnipotent God, who has declared in accents that ought to penetrate into every heart that *life is worth living*, when entered upon in a right spirit and with due preparation.

CYCLING IN ITS RELATION TO HEALTH.

By W. Armstrong Willis, Monmouth.

No apology whatever is needed for dealing with cycling in the pages of a medical periodical, for an increasingly large number of medical men are taking to it, and are recommending it to their clients. At the same time an almost incredible amount of stupidity still prevails, and many apparently well-informed people are ignorant of everything pertaining to cycling. They look upon it as costly, dangerous, and laborious, and fail to see that it is capable of being turned to the greatest possible use in every-day life. Country clergymen and doctors should use tricycles, if not bicycles, and would find them profitable and pleasant; rural postmen constantly now take advantage of them, and carry loads which would, but for their help, need a cart and a good horse. Patients are much in the habit of consulting their medical advisers, and looking to them for guidance, as to the expediency of cycling exercise; hence my apology, but I will first of all give what I may call my personal narrative.

I am within a measurable distance of thirty—that time of life, when, according to many modern medical authorities, the heart begins to get weak, and exertion becomes dangerous unless indulged in very carefully and temperately, and even then only after special training; in short, though not yet exactly old, I see old age just ahead. My life, too, is a very valuable one, not perhaps to the world at large, nor to my large circle of friends—and I mean by friends those disinterested individuals who will always accept an invitation to dinner, but who don't seem to see that they are

the obliged, and not I—but to myself, and so I am very chary of it, and guard it all I can from everything that may injure or imperil it. When, therefore, my esteemed friend Dr. Crespi, of Wimborne, said to me one day, pensively, "You have ceased to grow longitudinally though not latitudinally; you ought to take more exercise," I was struck. I knew my friend's delicate sense of humour, and that word "latitudinally" commanded my respect; I took off my hat and bowed; clearly at twenty-seven we don't grow longitudinally, though some of us begin to expand, as we find to our cost when with three other individuals as nobly proportioned we seat ourselves in a railway carriage, intended to hold five, as a very mendacious inscription above our heads informs us, and we find that from the horrible vice of scamping their work the carpenters have left out a yard from the proper dimensions of the seats, so that there is just room for three comfortably, one at each end, and one in the middle, though a fourth can, with a mighty effort be squeezed in; where the fifth is to go I can't conceive—in the hat rack perhaps. "Exercise," I replied, "why I take no end—I pass much time eating and drinking, and very good and necessary exercise it is too; then I read the newspaper, look out of the window, and if I find anything very lively I skip the last French novel; what more would you have?" "You must," he replied, solemnly, "get a tricycle and use it regularly." Now I don't care to throw my hard earned money away on experiments, and dangerous ones too, on my precious life, and I had heard so much of the herculean labour of propelling a tricycle up hill, and of the catastrophe often befalling well developed riders of middle age, that is, on the border line between youth and that time of life when a dressing gown and an arm chair seem the proper thing, that I felt I was bound to protest. "Do you know," I rejoined, "that it is universally agreed that a brilliant future awaits me? My father fully counts on my retrieving the family fortunes, and as for my mother, she thinks that with the exception of John Ruskin, I am the most brilliant and accomplished of the coming men of the age. Mothers you know are always proud of their sons, and mine is no exception to the general rule; she knows my worth, and would not lose me for all the world." Here, I thought, I had posed my friend, but he was not to be silenced. "I will," he rejoined, "get you a tricycle, and you shall have the use of it as long as you like." A few days later a machine made its appearance, and then behold me, the great literary artist of the future, the delight of his mamma, and the admiration of countless friends, with some difficulty hoisted into the saddle; and there I sat, the thing would not stir, though I sat patiently waiting for it to go. "You must work the pedals," expostulated my friend; then I tried, and I was soon convinced that the man who invented tricycles to save human labour was a humbug. I tugged at the handles, twisted the steering wheel, and worked away frantically with my feet—the thing would not stir; then a happy thought struck me—"I will get off," I said, "and push it, that will be good exercise," and before anyone could stop me I was off, I mean I had got down, and I began to push, but so stiff were all its joints that I soon found that would not do; besides I was to ride the tricycle, not carry it; a wheelbarrow full of stones would have done as well for the latter purpose. Then the thing would not go straight when it did begin to move; in half a minute I was against a wall, and before I had well started the horrid invention again, someone shouted, "Where are you coming, keep to your own side." Rather mortified, I mounted again, and made another attempt, when instead of going forwards the machine began to move backwards, and had I not hastily scrambled out I don't know what would have happened: the great luminary of the future might have been extinguished; the family fortunes would not have been retrieved, and John Ruskin, much to my mother's chagrin, might have been left in undisturbed possession of the literary arena.

But an Englishman never knows when he is beaten, though sometimes he runs away before fighting begins to save time, and I resolutely tried again. Rome was not built in a day, and I could not expect to become the equal of Holbein and Marriott the first time I tried. Comforting myself with the reflection that I resembled the heroes of the Consular Guard at Marengo, whose troubles, however, only lasted a few hours, while mine endured for days, if not weeks. I stuck to tricycling, and now I feel that I have added another to my many accomplishments of person and mind. Behold me then a graceful wheelman ready to dare anything and break any record. When I hear of any specially notable feat I ask myself, "Could I beat that?" I daresay I could, if I only tried long enough—perseverance will move mountains, but so far I have not won any prizes and not appeared in print as a champion of cycling. When I heard that my friend Richardson, of hygeian and tricycling fame—cold water Richardson—talked of Holbein's magnificent achievement—324 miles in twenty-four hours, on one of Hillman's Premiers—I turned the matter over in my mind. I was not sure that I could have done better, though I daresay with proper training, on good roads, I could have done the twenty-four miles, if I only started early enough in the day, and gave myself plenty of time. No, I don't somehow fancy racing and breaking records would be decorous on the part of an elderly gentleman who is growing latitudinally (I like the word, it is so suggestive and elegant), but I will guarantee to keep up with anyone, champion or amateur, who goes no faster than myself, and that is my challenge to the whole world.

My personal narrative being told, and the steps related which took me from the painful and timorous beginning of my career to my present exalted position as the possible record breaker of the future, I must deal with the matter more generally and for the benefit of the many country and town doctors, who want some information from an expert, and that information I gladly offer them.

The Rev. R. A. Chudleigh, in a capital paper in *Farm and Home*, of July 20th last, excellently summarised everything that could be said on the subject for the benefit of beginners. Indeed, I don't know that I could have conveyed that information very much better and more lucidly myself, though one never knows what one can do till one tries, but I have no intention of trying. My readers are referred to his charming paper. My principal points will be these—is tricycling safe, pleasant, useful, and easy?

As for its safety, with moderate care accidents are almost incredibly rare, and chiefly occur from turning sharp corners rapidly and going down hill too quickly, and, occasionally, from collisions. Even the latter are usually preventible. Never mind, although your life is heavily insured, and the profession is greatly overcrowded, so that a few vacancies would be welcomed, go round corners quietly, giving them a wide berth; go down hill cautiously, taking care that you have ample brake power, and be exceedingly cautious in passing carriages. If you will persist in trying to force your

way between two carriages close together, as you can't very well sweep both carriages out of your path, though you will probably succeed in frightening the horses, which does not improve matters as far as you are concerned, you are pretty sure to come to grief; and if you try to tear round a sharp corner you will infallibly capsize, and there will be work for the tricycle mender and the doctor—the latter, if you happen to be a surgeon, would be too bad, for dog won't eat dog—I mean doctors don't charge one another—and the reward which sweetens labour they could not look for from attending one another. Nevertheless, with reasonable care and after a little—a very little—practice, cycling is as safe as walking, and bicycling is even safer than tricycling—collisions are rarer, and corners can be more safely turned.

As for the pleasantness of the exercise, that depends a little, a very little, on the roads and the hills. At first cycling is a painful effort, though the first day is the worst, and facility rapidly comes with practice; but pain and effort do not last many days, and by beginning with a mile or two a day, and gradually increasing the distance covered, the time soon comes when even a man who has ceased to grow longitudinally will get over thirty or forty miles without turning a hair, without conscious effort, and without the smallest subsequent fatigue. Then there is a singular, indeed an indescribable charm in the rapidity of motion—flying along at seven or eight, or even ten miles an hour, and so bringing many places within easy reach, which were before impossible to get to; and that rapidity of motion is compassed by our own exertions, that is the best of it.

For country doctors a tricycle is a positive luxury: they can, when the roads are good, pay special visits, particularly on summer evenings, and so actually rest themselves, as it were, while sparing themselves and their men. A good wheelman would run a dozen miles altogether and pay an ordinary visit in a couple of hours. Hills are a drawback, certainly, but it is positively amazing how quickly the legs seem to gain strength. I only wish my aristocratic friends could see me flying along, courteously smiling at acquaintances. Hills! what are they to me now? nothing, though once, before I took to tricycling, I panted up them on foot, and when I reached the top, oh! it was dreadful to think of jolting down them to the bottom: positively, I was often tempted to try to roll down them, only I might have rolled into the ditch, or under the feet of spirited horses, and neither would have been pleasant nor particularly safe; now, the steeper the hill the greater the pleasure, for going down, on a first-rate tricycle, with good brake power, is so soothing. I throw myself back in my saddle, half close my weary eyes, and only wish my mamma could see the future Ruskin gliding swiftly, not to destruction, but to his destination, that brilliant future which I am more and more convinced awaits me. When the country is hilly, well, the hills must be surmounted on horseback, in a carriage, on a cycle, or on foot, and with a proper machine it takes a good steep hill to stop a practised cyclist.

As for the utility of cycling, well, I sometimes go in to my friend Dr. Crespi's, taking a large parcel of books, which, not even the certainty of being forthwith recognised as Ruskin's successor would induce me to carry, and I feel no inconvenience, and I have often carried heavy packages weighing thirty pounds; mile after mile I fly along, not giving the burden under me a second thought, and doing the pedalling automatically, going at double the rate I could have managed on foot, I mean which I could have reached in those days when, not having ceased to grow longitudinally, the rapidity of my movements delighted and surprised my friends, especially when, as an infant, I sometimes missed my footing and rolled down from top to bottom of a couple of long flights of stairs.

A few hints are necessary on the choice of a machine. A learner should use hired ones; they are used to being upset, and it does them no harm, besides, every rider requires his own machine, adapted to his height, weight, and to the special character of the country. For busy doctors who have no wish to break records and to figure in the annals of cycling, great speed and endurance are not requisite; indeed, I should hint at the prudence of not getting over the ground too rapidly, or special visits, at very inconvenient hours, will have a tendency to multiply, and the man who boasts that he can do his twelve miles an hour will have plenty of opportunities of putting his powers to the test; people will send for him just to give him extra opportunities of showing his skill to the greatest advantage. Every rider should choose a good, easy, strong modern machine with efficient brake power, a comfortable seat or saddle, bright lamps, and places for carrying a bag or a parcel: he should not lend it to anyone, but keep it for his own use, and it will get to know him and he it.

A medical man very commonly after giving his patient his prescriptions and an elaborate diet-card concludes with the remark "You must take plenty of exercise." It is a very sensible and proper corollary to his previous recommendations, yet when people are not rich, it is not easily carried out. If a man is young, at leisure, and well-off, then nothing is simpler than to mount his horse, take to boating, or carry out the command by frequenting the cricket or football field; to large numbers of both sexes whose sight is good there is also the tennis lawn. However, for various reasons, it will be often found that for many health-seekers these ordinary relaxations of our British youth are not available. Excluding horse-exercise as an expensive, and to many an unattainable, luxury, many a stout middle-aged man is not desirous to appear in the afternoon of life in the attitude of a learner of what he considers, perhaps too frivolously, as "games." Those acerb young gentlemen, who wrote smart letters in a recent newspaper correspondence about the compulsory athletics of the most famous of our public schools would scarcely be indulgent instructors of football, cricket or boating to an elderly man, urged by his doctor to "take exercise." As to pedestrian exercise, nothing is better than a brisk walk, amid pleasant scenery, with an object for it, or an agreeable companion; nothing is more delightful, exhilarating, or of higher tonic value than a tramp across country, over hill and dale. Unfortunately, it is not easy to obtain all, or even any of these accompaniments, absolutely necessary as they are to make a walk of any good from a medical point of view. Many of us have melancholy recollections of those walks, called "constitutional," a word which in its time has covered a hideous amount of fatigue, ennui, and weariness. Pounding along a filthy country road for five miles out and five miles in, for exercise, even in youth, when we have health and strength as our capital in the Bank of Life still undrawn on, is a fatiguing, wearisome performance and penance. The solitary student to be met taking his daily "grind" along the level roads near Cambridge rarely seems, to judge from his facial expression, to be enjoying himself; much less will a person of maturer years, and presumably decreased powers of active breathing

and motion, like such exercise as can be taken on foot, for a long period. Walking for many is productive of much discomfort, and it is hard to imagine any good result accruing from exertion, which causes the middle aged, those approaching thirty, to complain of exhaustion, tender feet, swollen ankles, shaken knees, and not uncommonly a bad headache into the bargain. Now for these poor creatures, undoubtedly cycling may be a blessed prescription; it is a capital exercise for the invalid and an invaluable way to keep the robust in health; it must be added that "cycling" in this article mainly refers to the use of tricycles. Tricycles have a great and obvious advantage over bicycles, they are suitable to both sexes, and may be used with satisfactory results by man, woman and child. Little exists requiring learning, and two minutes suffice to acquaint the novice with the arts of steering, putting on the brake, and pressing the treadles with sufficient force to obtain the required motion, especially if the beginner has not daunted himself by reading any of the sadly faddy and elaborate directions given in manuals for novices. It is perhaps well not to overdo it at first; a beginner ought to limit himself or herself to two spells of half an hour each for the initial attempts on the tricycle, gradually increasing with the learner's growing facility and enjoyment of the exercise. It is impossible to to lay down, in a general account like the present, any hard or fast rule as to distances and time of accomplishing given distances to be attempted by an average man or woman. The records of athletes are as suprising on the tricycle as they are in every other modern field of championship; they are to be taken by ordinary cyclists as horrid warnings and by no means to be considered worthy of emulation. Roughly speaking, a middle-aged man or woman, on an average machine, with a fair road and no opposing wind, will find seven miles an hour a pleasant rate of progression. From twenty to five-and-twenty miles will not be excessive if taken in two halves, with a suitable rest intervening. Personal experience points out clearly to me that the pleasantest of all exercise, and the least tiring, is a combination of walking and cycling. A person can cycle ten miles, take a brief walk, or do a little shopping, and return ten miles to his starting point, without experiencing the least fatigue. Tricycling and walking of course bring into play different sets of muscles; when the same muscle may be used in both processes, it is in a somewhat different way. This accounts for the rest experienced after cycling or walking, or vice-versa. In cycling the whole weight of the trunk of the body is taken off the lower limbs, while the concussion caused by the descent of the foot on the ground is prevented—a great saving; during any ordinary effort on a cycle there is no strain on the muscles of respiration. The work is done by the lower limbs, and without strain of tendon or friction of the sole of the foot, or weariness of the ankle and knee. Whenever a rider feels stomach-exhaustion from riding, is unable to take food with appetite, or digests slowly after the ride, he is told as plainly as words could tell him that his nervous tone, at the centre of life, the stomach, is exhausted, and that he had better do no more until he has rested completely.

There are some common-place suggestions which are quite worth while impressing on the beginner, who—especially if feminine—may be in need of some initial counsel. To begin with, it is not rational to go round corners at full speed: if your steering wheel is in front, lean forward going down hill; if the steering wheel is behind, it is wise to throw one's weight back, for unless this wheel has a firm grip of the ground, the steering down hill may be uncertain, and loose stones or inequalities in the road may prove a source of danger. Going down hill, if by chance the feet get off the treadles, it is never worth while to try to replace them; in attempting to get the feet on again, attention is often diverted from the steering, and one is landed in the hedge or on the road; at all times looking over one's shoulder is to be avoided as an unfailing danger. It is to be borne in mind that however rapidly the cycle is going, perhaps hurrying one into some approaching danger, at the risk of a skinned hand, one can save one's skull by laying one's hands and arms on the tyres of the two wheels; but this of course should only be done in an emergency, when one is rushing into a collision, or about to massacre innocents in a perambulator. The questions of saddles and broad seats is rather hotly debated: experienced riders prefer the saddle, but the broad seat is quite free from the reproach of perinæal pressure, which is sometimes hurled at the former. As to clothing, in this—as in all other active exercises—it is well to have flannel next the skin; a hard hat would be an undoubted advantage if one were thrown, as it would ward off or deaden a blow to the head. For men, knickerbockers, and for women the "divided skirt," have many and warm advocates; these are useful adjuncts, but no distinctive costume is absolutely necessary for cycling; this is a great advantage for those timid people who have a natural dislike to make "guys" of themselves. It is found by experience that the great charm of cycling is its exhilarating influence on the spirits; the sense of rapid, unjarring movement through the air has the most cheering effect, and few exercises, in so short a time, so wonderfully relieve any feeling of mental depression or brain weariness. It is, where practicable, an invaluable sedative, and should be tried by those numerous victims of insomnia, that complaint which may almost be called the "*maladie du siècle*," for it is certainly a great help in inducing sleep, and a general feeling of tranquil well-being.

Last Tuesday, in my ardour to be thoroughly posted up in the latest advances of cycling, I made my way to the largest cycling works in the world—those of Hillman, Herbert, and Cooper, of Coventry—and picked up all I could about the present and future of the art, and when I left was considerably wiser than on my arrival. At the risk of telling some of my readers stale news I will give them the cream of what I gathered. *Sociables* and *tandems* are not often made now; while bicycles are rapidly leaving tricycles out in the cold. This very year the number of the former has enormously increased, and probably seven are made for one tricycle. Prices have not fallen for good machines, though those now made are better finished, last longer, and are easier made. As everyone knows, the size of the machines in use has been much reduced of late, so that many of the best modern ones look like toys compared with the large unwieldly things of a dozen years ago, and in consequence of the small size of bicycles many people now commonly ride them who, till recently, would never have ventured upon anything so risky, so that the proportion of tricycles will certainly decline more and more rapidly.

Dr. Richardson told a friend of mine that he was using a tricycle weighing only fifty pounds, and of course such machines can easily be made, but they are far too light for the wear and tear of ordinary roads, and are not to be recommended: from seventy to eighty pounds is a fair

average weight, and it is not found to be any great effort to propel such a machine. A great modern step was the introduction of ball-bearings, that is, tiny steel balls, working in double grooves, and lessening friction to a notable extent: wherever there is motion ball-bearings can be used, and the pedals can be fitted with them.

As for its relation to health, I have surely said enough; anyone who can walk upstairs, or climb the most gentle elevation, can tricycle, even if he cannot bicycle, though the latter is very much easier in these days of safeties than commonly supposed. Effort there is practically none; and Richardson's estimate that one mile on foot, or two on horseback, is more fatiguing than six on a cycle is perfectly true; indeed, with the recent unparalleled advances in cycle manufacture, one might say that on good roads, one mile on foot, or three on an easy horse, would try one more than nine or ten on a cycle.

Yesterday I met my good friend Dr. Jones, of Mudtown. He is very decidedly stout; indeed, if I look like a small mountain, he looks like a very large mountain indeed. Well, I began telling him of my recent achievements as a wheelman, when my friend remarked that every doctor ought to have a good modern tricycle. He had had one for two years, which, he said, was worth more to him than anything he had ever bought in all his life. He had given twenty-two guineas for it, and thrown in a tricycle of older fashion; "but," continued Dr. Jones, "there is not a hill that I can't get up, not a visit that I can't pay on it: the only thing that beats it is a convenient train, and when I can get a good train I don't cycle; but barring good trains the cycle beats all else."

And if good for the doctor, the young, the strong, the active, in short for all not growing longitudinally, how good for invalids: to them time is no object; they can have their comfortable machine, settle themselves in it, and work on steadily, choosing the easiest and best roads, and so fully vindicate the value of cycling as a means of health, as well as the most delightful of all amusements.

THERAPEUTICAL NOTES.

From our Berlin Correspondent.

Lassar's "Hair Cure"—Chloroform in Whooping Cough—Cocain Poisoning—Tannic Acid for Burns—Iodoform in Chronic Cystitis—Iodoform in Tuberculosis.

Dr. Eugen Graetzer, of Sprottau, publishes in the *Therapeutische Monatshefte* an article on Lassar's cure for alopecy. He draws attention to the fact that alopecy and its treatment is more neglected by the public and medical men than any other department of the art of healing, and that it is generally not even looked on as an ailment, but more as a kind of blessing from heaven, towards which stoic resignation is the only thing to be done. Lassar, however, published a paper on "Hair Cures," in which he strongly recommends his method, which proved to be of excellent service in more than a thousand cases, not only of alopecia pityrodes, but also of area celsi, a disease which, he thinks, is highly suspicious with regard to contagious properties. The treatment, executed by a specially-trained hand, is day after day continued, for at least six to eight weeks. It consists of the following different stages:

First Stage.—A strong tar soap is applied to the scalp for at least ten minutes.

Second Stage.—Removal of soap by a tepid water douche, the water to be gradually cooled, the scalp to be well dried afterwards.

Third Stage.—The scalp to be shampooed with the following solution:

℞ Hydrarg. bichlorid. corrosiv. ..... gr. x.
Glycerin. .....
Spirit rect. .....āā ʒij.
Aq. distill. ..... ʒv.
F. fiat solutio. S. For ext. use.

Fourth Stage.—Shampooing of head with absolute alcohol, to which half per cent. of naphtol has been added.

Fifth Stage.—The following solution to be well rubbed into the skin:

℞ Acid salicyl. ..... gr. xxx.
Tinct. benzoic..... ʒi.
Ol. ped. taur. .....ad. ʒiii.

Graetzer found this treatment most useful and efficaceous in private practice, and therefore does not hesitate to recommend it to the profession. He says that with such a powerful method of treatment in view the present indifference of medical men with regard to the treatment of alopecy ought to be given up.

Dr. Schilling, of Nürnberg, published a new method of treating whooping-cough, consisting of inhalations of chloroform water. Salkowski discovered that aq. chloroformi (1 in 200) possesses powerful antiseptic properties. On the latter Schilling relied in his novel kind of treatment of whooping-cough, which he tried in sixty-two different cases with children from ten weeks up to twelve years of age. As inhalation apparatus he uses a steam spray, the boiler of which is charged with one tablespoonful of water to which twice as many minims of purest chloroform are added as the child counts years. If after eight days' inhaling there is no marked improvement the dose is increased to twice as many drops as the child counts years. The glass bottle of the spray is filled with plain water, no chloroform is added to this. As chloroform is dissolved in water only in the proportion of 1 to 250 there is a surplus of chloroform at the bottom of the boiler, which, on heating, is evaporated, partly even before the water is boiling. This is the reason why inhalation ought to be commenced before the boiling point is reached. Each time the inhalation is continued until all water has evaporated, and the inhalation is repeated four times a day. With such treatment the further progress of the disease is arrested after a few days, and in the course of a week a marked improvement usually takes place—the paroxysms becoming less frequent and less violent. In half of the cases the paroxysms disappear entirely after fourteen days, and only slight bronchitic symptoms remain. This final stage of bronchitic catarrh was reached after one week in four cases, after two weeks in twenty-eight cases, after three weeks in twenty-one cases, and after four weeks in eight cases. Therefore the results of this new treatment may be designated as very good. Inhalations of carbolic acid, formerly used by the author, did not give such results. Antipyrin sometimes acted very promptly; in other cases, however, it failed entirely. Similar questionable success was obtained by the much-praised nasal insufflations of benzoate of sodium. The author tried several times to give pure chloroform as inhalation. Applied in this way the chloroform acted very beneficially.

Chloroform water, ♏vii. ad. ʒiii., given internally, had no effect whatever neither in whooping-cough nor in any other illness.

A case of serious cocain poisoning in a child ending in complete recovery is reported by Dr. J. Stein, of Saaz.

He applied to a girl of two and a quarter years a suppository, consisting of oil of cocoa and three grains of cocain. One hour after application the child woke, became excited, threw about her arms, and talked constantly. The doctor saw the girl two and a half hours after application of the suppository, and found the child in a state of great excitation; movements were made with the hands similar to the involuntary movements observed in chorea. Respiration was increased, radial artery showed high tension, pupils were slightly dilated. The treatment consisted simply of cold bandages applied to the head. Four hours after application the child became quiet, and on the following day it was all right again.

Tannic acid is now being highly recommended for the treatment of burns and scalds. Limbs where the whole epidermis was removed healed rapidly under this treatment, which consists of the following: A sponge is soaked in a five per cent. solution of tannic acid and pressed out over the granulating surfaces. A soft lanolin ointment, with or without admixture of tannic acid, is thereupon applied. Pain disappears, and healing is rapidly effected. On changing the ointment dressing the sponging with tannic acid is repeated. The method is said to be specially suitable when large surfaces of the body are affected.

Professor Mosetig-Moorhof recommends, in the *Wien. Med. Presse*, the following emulsion for chronic cystitis:

℞ Iodoform ..... ʒ ij.
Glycerin. ..... ʒ ijs.
Aq. dest. ..... ʒ iii.
Gum tragacanth ..... gr. iv.

Half an ounce of this emulsion is suspended in a pint of warm water. This is injected into the bladder, which has previously been washed out with plain warm water. The process is repeated every three days. After three or four applications the cystitis is said to be cured, or at least very much improved.

Iodoform oil is at present used for treating tuberculous affections of joints and bones. This oil is injected into the affections of joints and bones. This oil is injected into the tissues just like a solution of iodoform in ether, which, however, has been given up for reason of its extreme painfulness, and of its occasionally causing gangrene. A 20 per cent. mixture of iodoform with olive oil, prepared fresh for each injection, is used. Part of the iodoform will decompose if this mixture is kept for some time, such decomposition being easily found out, as it causes a reddish-brown coloration. 30-45 m. of this mixture are injected every eight days on different places, by the aid of a Pravaz syringe. Previous careful disinfection of the skin is advisable.

Reviews.

Congestive Neurasthenia, or Insomnia and Nerve Depression. By E. G. Whittle, M.D. Lond., F.R.C.S. Eng. London: H. K. Lewis. 1889.

When the history of medicine comes to be written the present will surely deserve to be described as the age of infallible cures. The elixir of life has certainly not yet been prepared, but have we not good grounds for supposing that we have most of its ingredients at hand in our laboratories, medicine chests, and other armamentaria? The minor ailments—the thorns in the flesh—that remind the strongest of us that we are but mortal, are made to vanish by the ingestion of a homœopathic globule, delicately "sugared o'er" so as not to offend the most fastidious palate: diseases more formidable and intractable yield to the gentle touch and exhortation of the hypnotiser; the inexhaustible derivatives of coal-tar seem to provide a remedy for every symptom that human pathology can produce. No longer

> "Diseases desperate grown,
> By desperate appliance are relieved;"

they yield to the mildest, the blandest of remedies. But yet we are not happy; our hospitals are still full and overflowing; sickness still brings grief and poverty into bright and prosperous homes; still the young and hopeful are stricken down in the midst of their activity. The elixir of life is not complete; an *adjuvans* or *corrigens* is still wanting, and many are searching for it, with more or less success. Dr. Whittle has bestowed no small attention on a form of disorder that most of us have probably been called upon to treat, but for which, unlike most of us, he thinks he has found a remedy which acts *cito tute et jocunde*. The disease is a form of hypochondriasis with insomnia, characterised by general plethora, throbbing carotids, and a feeling of heat about the head—"congestal neurasthenia;" the remedy is leeching. For the full description of the complaint and its cure we must refer our readers to the book itself; of the value of the treatment advocated, we cannot speak from personal experience, and therefore hold our peace. We will say of the book, that it is written in a style of the most refreshing optimism, that it is very agreeable reading, and that the printing and the paper are everything that can be desired. It is pleasant to know that one of the author's patients "came lightly and gaily up to him in the morning with a laughing welcome, and the declaration that he had had a good night, and was himself again." But we may be pardoned for questioning the dogmatic assertion of the author when he declares, "Bleeding, I have no hesitation in saying, was the only means by which his cure could have been attained." We confess we have some deeply-rooted prejudices against the practice of blood-letting, except in cases where life is threatened by some form of toxæmia, prejudices which are not lessened by Dr. Whittle's silence with regard to its physiological action. T. R. Bradshaw, M.D.

The Purchase of Women: the Great Economic Blunder. By Dr. Elizabeth Blackwell. London. 8vo. pp. 42.

Dr. Elizabeth Blackwell is a bold woman! albeit, in the very best sense of the word—a courageous out-spoken lady! With the confidence of conviction, she lays bare the enormity—moral and social—of fornication, or trade in women, and exposes the real meaning of those relations of the sexes which are commonly known under the term "ordinary immorality." Thus, Dr. Blackwell proceeds to reason, "Many persons who would shrink from the guilt of being the author of a first seduction, or of running the risks of legal prosecution, will not hesitate to engage in 'ordinary immorality'—that is, they will without scruple purchase the temporary use of a consenting woman for a little money; they will justify the transaction by the plea that what women will sell, men may buy. They may even consider that they show a little contemptuous kindness to women in such buying, as industrial conditions press more heavily on women. Women also accept false theories of human nature, that blaspheme their Creator, and degrade the exalted rank of motherhood by welcoming profligates, and sacrificing their daughters in mercenary marriages."

We have used the expression "trade in women"; we may here explain its employment as used by the authoress. "If temporary bargains are made, either expressly or tacitly,

by which one party gives money to another for a certain return, such a bargain is trade. If few such bargains are made it is a limited trade, if many it is an extensive trade; but in each case the transactions are equally trade, and are necessarily subject to the laws which govern trade. If, therefore, women are made the subjects of temporary purchase, they become the subjects of trade. Now trade is always directed by the rules and customs prevailing at the time, and the economic aspect requires to be studied, for the laws which govern trade are not fanciful theories, but very real practical facts which lie at the foundation of our social institutions, and silently mould our everyday life." These data are applied by Dr. Blackwell to the exposition of problems in political economy, and are applied to the question of ordinary immorality, equally with their relation to co-operation in the production and distribution of wealth generally. Dr. Blackwell very forcibly observes: "It is necessary to realise the overwhelming and illegitimate power of money in the present day if the condition of any trade is to be justly judged, and the responsibilities for the evils of a vicious trade rightly apportioned. In the terrible trade which converts the human body into a marketable commodity, it is no figure of speech, but a very weighty fact that vicious men are the capitalists. The responsibility of the position must be recognised."

Dr. Blackwell points out the difficulties which surround honest industry, and press with increasing force upon women's labour, compelling "a moral heroism to resist the special temptation which crowds upon them. . . . The contrast between the ease with which the wages of sin may be gained, and the laborious, even crushing methods of honest industry becomes an ever present and burning temptation to all working women" (p. 29). The various circumstances under which temptation to sin is forced upon the insufficiently remunerated working woman, are strongly, but truthfully, put by Dr. Elizabeth Blackwell, while the guilt of this transgression of moral laws is vividly brought home to men. "There cannot be," adds the authoress, "one moral law for human beings which is at the same time of unequal application to them. . . . Divine law admits of no exception; it cannot contradict itself. It is equally binding on the weakest as on the strongest, on the man as on the woman, or it is not law. If men are so constituted that they can grow to the full stature of manhood without obedience to the law of purity, then the moral law of purity does not exist for them, because it is not a necessary method of growth to their highest human development; their nature is not adapted by the creator to the moral laws, its influence over them is weakened, its absolute authority destroyed" (p. 41). We have thus placed before our readers the solemn consideration of a most solemn subject, as nearly as possible in the author's own words, conscious that we could not add force thereto by our own more feeble comments, and trusting very sincerely that the "purchase of women" may fall into hands of those who will read, mark, learn, and inwardly digest it.

W. B. Kesteven, M.D.

Short Notices.

Four Reprints. By Adolf Bronner, M.D. London, 1889.

1. *Antiseptic Ophthalmic and Aural Surgery* (reprinted from *British Medical Journal*, February, 1889).—"In speaking of antiseptic surgery," Dr. Brönner observes, "we mean the method of operating or of treating a wound: firstly, so that we may prevent the entrance of micro-organisms into the wound (aseptic surgery); and, secondly, that we may destroy or arrest the development of the micro-organisms which may be in or near the wound (antiseptic surgery)." To illustrate his ideas of antiseptic ophthalmic surgery, Dr. Brönner refers to the antiseptic precautions used at the Bradford Eye and Ear Hospital, under which, out of over 900 major operations, in two years, there was not a single case of suppuration. In aural surgery, it is, of course, "quite impossible," adds Dr. Brönner, "to perform an aseptic operation, as the wound is always in communication with the ear or throat." Antiseptic precautions, however, have been taken to prevent the development of the micro-organisms in or near the wounds.

2. *Local Treatment of Non-Suppurative Diseases of the Middle Ear* (reprinted from the Provincial Medical Journal, June, 1889).—The author introduces his observations by the following remarks: "The greatest triumph of otology in late years has been the fact that we have, at least, recognised how very intimate the relations are between the diseases of the nose and those of the middle ear." This passage is the key-note of the essay. Obstructions of the nares, such as may be caused by swelling of the mucous membrane, or by polypi, are among the principal morbid conditions that Dr. Brönner treats of in this place. We note, however, the following observations: Roughly speaking, we can divide the non-suppurative diseases of the middle ear into three classes—acute catarrh, chronic catarrh, and dry catarrh or sclerosis. The author points out the difficulty of distinguishing between diseases of the middle or internal ear, and points to the uses of the tuning-fork in the diagnosis of these affections. The author's observations under this head are purely practical, and will prove useful. The directions for the treatment of catarrhal disease will also be found of service.

3. *Pseudo-Hay Fever* (reprinted from the *Lancet*, July, 1889).—The affection here referred to, consists in nervous or vaso-motor rhinitis, and is, together with its treatment, fully treated of by Dr. Brönner, and illustrated by record of cases. "Chronic hypertrophic rhinitis," the author observes, "is a very common disease. In bad cases it renders the life of the patient perfectly miserable, often compelling him to give up his occupation and leave his home in search of a better climate. . . . It also frequently brings on or keeps up inflammation of the middle ear." In all cases of chronic disease of the middle ear, the author, therefore, urges the examination of the Eustachian orifices.

4. *On the Diseases of, and the Operations on, the Mastoid Process* (reprinted from the *Medical Press and Circular*, July, 1889).—The affections of the mastoid, which are treated of in these pamphlets, "roughly speaking," periostitis; catarrh and empyema of the mastoid cells; sclerosis; caries and neurosis. The remarks upon these lesions of the ear, formed the subject of a paper read by the author before the Yorkshire Branch of the British Medical Association at Bradford, in March of the present year. Symptoms and treatment are considered as fully as the limit of a short paper admitted. Among the principal facts to be noticed, as stated by Dr. Brönner, are: extensive and dangerous changes may be going on in the mastoid process without any well-marked symptoms; these affections frequently give rise to intra-cranial inflammation, pyæmia, general or local inflammation; in all chronic cases the periosteum and osseous tissue of the mastoid process ought to be carefully examined.

W. B. Kesteven, M.D.

The Provincial Medical Journal,

DECEMBER, 1889.

One of the most important advances in modern surgery is the operative surgery of the brain; and this, no doubt, is due in the first place to the researches on cerebral localisation by Ferrier, Yeo, Hitzig, and others; and in the second, to the possibility of opening the skull, and interfering with the brain and its membranes, adopting the principles laid down by Lister. Whether these principles are dependent upon the prevention of air-germ development, or are essentially those of absolute cleanliness and thorough drainage, need not be here discussed; but there is no doubt that trephining and brain surgery have been very haphazard, though often startlingly successful, from the days of Percival Pott to rather recent times. But in order to enable the surgeon to find the spot which the physician indicates is the seat of disease, we have been groping after useful landmarks to guide him in operating. The difficulty of securing these is obvious, for the scalp possesses few that are stable, and the sutures of the skull are difficult to identify through the scalp. And allowing that some fixed points can be secured, we have then to find how to determine the proportionate distances from those of certain important brain areas and cardinal points. The methods hitherto given have been unsatisfactory, involving, as they do, intricate surface lines and measurements by inches and fractions of an inch from certain points; and we are glad to meet with an important contribution to the subject by two scientific English surgeons at the meeting of the Anatomical Society, and reprinted in the *Journal of Anatomy* (W. Anderson and G. H. Makins, "Experiments in Cranio-Cerebral Topography").

Their object was twofold: (1) To map out the latitude and longitude of the cranium by means of a few simple lines running between points that are capable of precise definition on the scalp—these lines and their relation to the brain surface not to be materially affected by variations in form and dimension of the skull. (2) To register the relations of these lines to the principal fissures, etc.; to learn the normal range of variation in the position of these fissures, etc.; and to establish a series of surface points which shall indicate the mean position of certain parts of these. As a first result of these inquiries, certain "guiding lines" were devised, and these are the ones from which the proportionate measurements have to be taken on the scalp, and must therefore be taken careful notice of. The first is called the mesial, or "sagittal line," and extends from the glabella to the external occipital protuberance. The middle point of this is called the mid-sagittal point, and is of much importance. The second line is nearly parallel in direction with the face, and this they call the "frontal line." This runs from the mid-sagittal point to the depression just in front of the tragus, at the level of the upper border of the external auditory meatus. The third, or "oblique line," runs from the outer angle of the orbit (external angular process) to the junction of the middle and lower thirds of the frontal line, and is prolonged backwards about an inch and a half. The authors seem now to have adopted the term "squamosal," instead of oblique. Carrying these three lines constantly before us, we are led to notice that the cranial sutures, ridges, and eminences, are related to them and to the subjacent convolutions with a good deal of uncertainty in different subjects, and even differing considerably on the two sides of the same subject. All that is possible for an anatomist is to indicate upon the scalp an easily defined spot which shall hold a central position with regard to all the probable variations of the particular brain locality studied. Taking now the fissure of Rolando, it is found that the safest plan for trephining so as to reach the upper extremity of the fissure will be to fix the central point of the trephine three-eighths of an inch behind the mid-sagittal point. For the lower end of the sulcus, perforate in the squamosal line three-eighths of an inch in front of the "squamosal point," or crossing point of the frontal and oblique lines. The commencement of the fissure of Sylvius may be found on the squamosal or oblique line, about an inch and a quarter behind the external angular process of the orbit, or five twelfths of the distance from the angular point to the squamosal point. The bifurcation of the fissure is along the same line, but about an inch and a half to two inches behind the external angular process, or seven-twelfths of the distance from the angular point to the squamosal point. The course of the limbs of the fissure is fairly definite, but the termination very difficult to define. However, the parietal eminence roughly indicates its position.

These are the chief fissures studied in this inquiry, and the results will be of practical value to surgeons in operations on the brain. They seem based on a scientific system, and to be more workable and trustworthy than any plan we have met. The topographical chart which accompanies the paper is just what is wanted by the surgeon, and might be made more complete by indicating the subjacent convolutions and fissures in coloured ink. In the same way we would suggest marking the position of the main sinuses and meningeal arteries, and then a still more useful plate could be produced for the guidance of the surgeon or student. Mr. Anderson and Mr. Makins are to be congratulated on the results of their inquiry, which, however, is capable of further extension.

They claim that the standard points selected by them are few, and liable only to a very small degree of variation in different subjects: that the "frontal" and "oblique" lines by which the course of the fissures of Rolando and Sylvius are mainly indicated, undergo changes of length and direction in association with variations in the size and form of the skull, and are therefore applicable for heads of all sizes and shapes, adult or juvenile; and that the test-points in the course of the different fissures are measured as far as possible in fractions of the length of the lines rather than in inches and centimétres, in order to secure a similar adaptation to crania of all dimensions. This rule is departed from

only in the case of the two extremities of the fissure of Rolando, where the necessary adaptive changes are sufficiently secured by the shifting of the frontal line. In a paper by the authors (*Lancet*, July 13th, 1889) will be found a long list of the different methods given by other observers for finding certain brain points by measurements from more or less distinguishable surface markings and processes, and one of the figures given shows the subjacent convolutions as we have suggested. A paper by Ludwig August Muller, of Frauenfeld, has just appeared on the same subject, and his method of mapping out the skull cap involves drawing a horizontal line from above the orbits, and a sagittal line. These are each divided into one hundred parts, and the corresponding tenths again united by cross lines. The seat of various brain areas is calculated from these lines. The adoption of percentages instead of fractions is an advantage, and has already been made use of by Hare and others; but the cross lines appear to us not definite enough, and the relation of the lines to the skull rather than to the surface is at first sight an objection. This, however, is hardly the case, for the points chosen are such as can be readily felt.

The *Medical Register* was compiled with the object of being able to distinguish qualified from unqualified practitioners—entry to it, entitling the practitioner to certain rights; as for instance, the power of recovering, in the courts, law fees. The *Register* was a necessary accompaniment to the new medical act, but it is all essential that this *Register* should be kept up to a true standard, and that we should have the correct names and addresses in it of all who are entitled to registration. We publish in this issue a very important announcement from the Registrar, and we would direct the attention of our readers to it for their own protection, and also for the purpose of assisting the Registrar in keeping the volume accurate. Many practitioners have, on occasions when registration would be valuable, found, owing to neglect or unacquaintance with the ordinance, that their names were not on the *Register*, and consequently they were deprived of certain privileges. We remember when the contest for the Medical Council was proceeding we were very much struck by the number of medical men who were not on the *Register*. They had changed their addresses in the town in which they were living, or changed their locality, the consequence being that their names failed to appear. The process of restoration to the *Register* involves some time. Certain forms have to be filled up in proof of identification, correspondence has to be entered on, and a considerable amount of extra labour is imposed on the officials of the medical council office. All this can be easily saved by attending to the acquirements as set forth by the Registrar. Many may think that there is no advantage to be derived from having a place in this official list, as unqualified pretenders are allowed to practise with impunity, and quacks and others practise under the eye of the medical council. It is true that the law is imperfect, but it does not affect the question. The unregistered practitioner cannot recover any fee or honorarium in a court of justice, unless his name appears on the *Register*. As a copy of this official guide to the profession is furnished to the law officers of the crown, this advantage alone should be secured. Again, in the filling up of all appointments in the public services, the *Register* is taken as the guide, so that here we have another reason why practitioners should conform to the law. Each year the Registrar publishes an appeal to the profession to comply with the requirements of the medical acts. One letter would suffice to notify any change of address, and we are not asking too much in expecting the profession to comply with this reasonable demand.

This question, as the French say, is again "in the air;" in fact, there never has been a time when it has been out of it, for if we look back at the files of the old journals for fifty years we find that the abuse of medical charity appears to be ever to the fore. The literature of the subject is enormous, and by this time it ought to have been thrashed out; but never before has it received such general attention. Individual writers have expressed their opinions, and we have had conferences, in which a number of earnest reformers have tackled the subject; but now it has excited the attention of the largest medical association in the world. The British Medical Association has referred the matter to the branches—*re* the resolutions of Dr. Rentoul, and we sincerely hope that some remedy will be devised which will rehabilitate the profession, and establish some *modus vivendi*. The profession may be divided into three classes: (1) the general hospital surgeons; (2) the special hospital surgeons; (3) the general practitioners. The question has to be considered from three different points of view, because the interests at stake are rather diverted. The most numerous class are the general practitioners who are not attached to hospitals; but their strength is not proportionate to their numbers, and their views and their interests are not likely to be considered when they come in contact with those of the other classes. Oligarchies have always succeeded in protecting their own interest, for there is an amount of cohesion amongst them which is a most important factor in the preservation of monopolies. The hospital surgeons build up their reputations by the charitable work they perform, and it is necessary for them to have a large number of patients from whom to select suitable cases for operation or treatment. The out-patient department is their hunting ground, and they look with disfavour on any attempt made to cut down this department. This is doubly true of the special hospital surgeon, so that here at once we have to face a very great difficulty—viz., to reconcile the conflicting interests of the hospital surgeon and the general practitioner. It is clearly necessary that we should have hospitals, but the question narrows itself down as to how the patients are to be recruited.

The present system, we have no hesitation in saying, is injurious to the great bulk of medical men. And we also

believe that it causes a great waste of energy on the part of the hospital surgeon, and there should be no difficulty in devising a scheme which would work advantageously for all sections of the profession. We would absolutely insist upon the abolition of the out-door visiting of all infirmary patients; and as regards the out-patient departments, there is but one opinion, that half the number might be cut off with advantage to all interested, patient as well as medical attendant. Dr. Rentoul's scheme is, we believe, unworkable, though we are in thorough accord with him in the spirit and object of his work, and the profession is indebted for the energetic and persevering manner in which he has set about his reformatory crusade. He has succeeded as only earnest men can succeed in bringing medical opinion to bear on the subject, and we have no doubt that when the opinions of the different branches are collected and collated, we shall have some practical conclusions which will bear good fruit in the future. If the British Medical Association be the means of diminishing the abuse of medical charity, it will strengthen its hold upon those who are its largest constituents, for it is upon this class that the pressure mostly falls. The starvation of the hospitals, caused by the multiplication of these institutions, must also be taken into consideration. It is not always beneficent to have too many hospitals. The first step to pauperisation is but too frequently taken by means of an out-patient recommendation. Independence is sacrificed; self-respect is weakened; and when the latter has gone, the downward progress is easy.

The contributions of the working man have not been an unmixed blessing, because, unfortunately, the donors of a few pence per annum, which in the aggregate amounts to a large sum, consider that they have a claim upon the charity they have contributed to, and they expect something in return for their donations. We publish in this number a letter from Dr. Rentoul, giving statistics of the number who apply for free medical advice, and it is simply appalling to find that we have such a host of indigent persons in England, apart altogether from the true pauper class. We published a few years back a number of essays on the causes of low fees in the profession, and these papers might be re-read with profit by those who are interested in this social question, for the writer's thoughtful and practical view thoroughly quartered the field, and accounted for many of the grievances of the profession. All complained of the abuse of medical charity. Various remedies were suggested, but there is one factor to be taken into account—viz., the want of union in the profession; and until this is cured no scheme will have any chance of success. The British Medical Association may be able to overcome this difficulty and bring about union, but without this union no scheme will succeed.

We have on several occasions during the past ten years written on the subject of the accommodation for the insane, and we have pointed out some of the evils of the existing system. For years we have been content with collecting together, into monster institutions, the demented, the imbecile, the epileptic, the maniacal, etc., and placing them under the superintendence of a medical man, to whom also is intrusted the domestic management of the institution necessary for the housing of the large number of lunatics in our counties. Some of our asylums have 1000 to 1400 patients under one medical superintendent, who is also general manager. It is true that there are assistant medical officers, but even with this assistance the medical direction is imperfect. This is one aspect of the subject. Another arises from the expensive manner in which these asylums are fitted up. Yorkshire, in its West Riding, has now three asylums: Wakefield, Wadsley, and Menston; the accommodation in each asylum being for 1400 patients. The style in which these asylums are built, and the surroundings, are simply extravagant; and we do not wonder that they are filled, or that friends of patients should be only too anxious to place their weak-minded relations in places which promise so much. The zeal of the medical superintendents is so well known that anything we have to say cannot detract from their merits; they are the creatures of circumstances.

The asylum by its name condemns the system; it means that Society is relieved of the presence of its lunatics, and that they are protected—finding a haven of rest and comfort, so that the curable and incurable cases find in the same establishment both treatment and protection. Some years ago the Halifax guardians, not being allowed by the Local Government Board to extend their buildings, and wanting accommodation for their ordinary sick, sent all their chronic incurable cases, to the number of 140, to Wadsley, and we believe a number of them are there still. The change was effected without loss to the guardians, as the grant of four shillings per head was received by the exchange. But this was simply turning Wadsley into a boarding-house, and crowding the establishment with a dead weight—increasing the responsibility of the medical superintendent without bringing into play the exercise of his higher capacity—viz., the application of his therapeutical knowledge to the cure of insanity. Other unions, no doubt, followed the same plan, so that we do not wonder at the rapid filling of our Yorkshire asylums. The Halifax patients were removed from very excellent wards, quite equal to the accommodation in general hospitals, but of course not to be compared in any way with the luxury of the modern asylum; so that these patients gained by the improvement in their surroundings; but they were not one bit better off as regards diet. They had gingerbread at Halifax and gingerbread at Wadsley, with this difference, that at Wadsley the gingerbread was gilded.

We trust that some steps will be taken to reconstitute the old system; to leave the imbeciles and demented in proper care in their own parishes, or in imbecile wards in connection with union infirmaries, taking precautions that they shall be treated as well as they have been at the asylums. This would relieve the asylums, and give the medical

officers more time to devote to cure and therapeutics. We in this connection welcome the attempt now being made in London to institute a hospital for the treatment of brain diseases. It is supported by practical medical men who know the imperfections of the present system, and judging by the support the proposal has received we shall probably have a hospital of this kind opened under the protection of the London County Council. It may be considered a reproach to our present superintendents. It may be said, have we not already hospitals of this kind? We have indicated already the objections to the old system. In due time the provincial county councils will move and convert the present *asylums* into hospitals, and the superintendents will have every reason to be content with the change.

Annotations.

"Forsan et hæc olim meminisse juvabit."

"THE PROVINCIAL MEDICAL JOURNAL."

During the year 1889 The Provincial Medical Journal was permanently enlarged to sixty-four pages, without any increase in price; and we are assured by numerous correspondents that with the increasing quantity there has been a corresponding increase of the quality of the literary matter. The journal is now established, and our only desire is to make it more useful; and as the publishers have most liberally responded to all our suggestions, we shall be able during the coming year to develop parts in which we have been weak. For instance, we have not given as much space to therapeutics as it deserves. We shall try to strengthen this section. The quality of the articles will be sustained during the year.

THE EDINBURGH SCHOOL OF MEDICINE FOR WOMEN.

Lord Kyllachy has awarded to the pursuers in the action against the Executive Committee of the Edinburgh School for Women the sum of £50 each, as a solatium for their expulsion from the school. His lordship said that Miss Jex Blake had overrated her position, and had endeavoured to exact too much from the young ladies who attended.

HORSE EXTRACTS *VERSUS* BEEF.

The scare about the use of dead horses and donkeys for the manufacture of meat extracts will for a time injure manufacturers of genuine meat extract, but the scare will only last for a time. Sausages are supposed to be made of dogs and cats: the sausage preserves its position, and is used as freely as ever. There are two points to be cleared up: (1) What becomes of the old worn-out horses that are sent abroad? (2) If used for meat extracts, is the extract injurious or beneficial? It is evidently a fraud to sell fluid or jelly under the name of beef, which is really made from the flesh of other animals; but apart from the sentiment and substitution, we should like to know the value of horse extract.

MARASMUS, AND OTHER VAGUE CAUSES OF DISEASE.

There is good work to be done in the clearing up of the nature of marasmus, and of the wasting diseases of children. Marasmus by itself is a general term which may mean anything. As it is very frequently used on the registration certificates of death, it must in a very considerable measure influence the Registrar's statistics.

THE MEDICAL DEFENCE UNION.

A metropolitan branch of the Medical Union has just been established in London, and the following members were chosen on the executive: Mr. Ernest Hart, Dr. Danford Thomas, Dr. Corner, Mr. Telce, Mr. Goodsall, Mr. Masters, Mr. Roche Lynch, Mr. Noble Smith, Dr. Fancourt-Barnes, Dr. Verdon, Dr. de Havelland Hall, Dr. Prior Purvis. The meeting took place at the offices of the British Medical Association, and Mr. Lawson Tait presided over a very representative gathering of metropolitans. It is, we believe, a well-known fact that large cities owe their vigour to the recruitment which takes place in the country, and this is thoroughly true in medical life. We provincials gave to London the finest medical organisation in the world, the British Medical Association; and we are now presenting her with another sound constitution in the shape of the Medical Defence Union, which provincial vigour has re-created out of the skeleton which came from the metropolis.

THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

The autumn general meeting of this Association took place at 11, Chandos-street, London, W., on Thursday, November 7th, 1889. Dr. Richard Fegan (Blackheath), President, occupied the chair, and among the other members present were Sir Thomas Crawford, K.C.B., Drs. Macnaughton Jones, Mapother, Gaven, C. Wells, J. S. Swain, James Donelan, Douglas Lithgow, W. Beech Johnston, J. J. Lough, F. J. Waring (Brighton), Richard Heath (St. Leonards), J. O'B. Williams, R.N., James Stewart, and P. S. Abraham. A presentation, consisting of an illuminated address and a handsome clock, was made to Dr. James Stewart, by Dr. Macnaughton Jones, on behalf of the members of the Council, in recognition of his labours as one of the hon. secretaries of the Association for the last five years, and as a mark of their personal regard. An alteration of rule vii., by which the Council would be empowered to elect an additional hon. secretary, was proposed and carried. On the proposition of Dr. Stewart, a vote of sympathy was passed to Dr. John Eadie, of Yeovil, a member of the Association, on the occasion of the false charge and attempt at "black-mailing" to which he has been recently subjected. A vote of congratulation to Sir John Thomas Banks, K.C.B., on the motion of Dr. Abraham, seconded by Sir Thomas Crawford, on the occasion of the distinguished honour of which he has lately been the recipient, was adopted with acclamation. In the evening fifty-four of the members and their friends dined together at the Holborn Restaurant.

MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The election of Mr. Jonathan Hutchinson as president of the Royal College of Surgeons of England was in every respect a fortunate one, as he possesses the confidence of the profession, and is in touch with its modern spirit. It is wise at times to bend, and this may be done with dignity, without yielding one iota of principle. Mr. Hutchinson by his address to the members, though he did not disarm criticism, or weaken the claims of the members to proper representation, yet conciliated and poured oil on the troubled waters. There is a possibility, with such a president, of effecting a settlement of the long-standing dispute between the Council and outside members.

THE COMPULSORY NOTIFICATION ACT AT LYTHAM.

At a meeting of the Lytham Commissioners, Dr. Fisher put in a clear and forcible way the objection to notification, applied to such a seaside and health resort as Lytham, and knowing Lytham we are forced to his conclusion, that he was acting in the best interest of the town in opposing the application of this Act. For Liverpool, Manchester, Leeds, and other large towns, notification may be advantageous, but the conditions at Lytham are not identical, and the arguments deduced from the general advantages secured in large towns are not applicable.

Dr. Fisher said that he had carefully examined the act, the main points of which were to be found in clauses A and B. Clause A provided that "The head of the family to which such inmate (in the Act referred to as the patient) belongs, and in his default the nearest relatives of the patient present in the building or being in attendance on the patient, and in default of such relatives every person in charge of or in attendance on the patient, and in default of any such person the occupier of the building shall, as soon as he becomes aware that the patient is suffering from an infectious disease to which the Act applies, send notice thereof to the medical officer of health of the district." Clause B said: Every medical practitioner attending on or called in to visit the patient shall forthwith, on becoming aware that the patient is suffering from an infectious disease to which the Act applies, send to the medical officer of health for the district a certificate stating the name of the patient, the situation of the building, and the infectious disease from which, in the opinion of such medical practitioner, the patient is suffering. Proceeding Dr. Fisher said: "In my opinion nothing whatever would be gained by its adoption, inasmuch as 'notification' has always been given voluntarily and gratuitously, and it appears to me to be quite unnecesssry so far as Lytham is concerned to make it compulsory, and in this opinion I find I am supported by the other doctors, the medical officer excepted. Taking this view of the question, there need not be any fear that the public will be dissatisfied with the decision of this Board, should it decline to give sanction to its adoption. Indeed, can it be supposed that Mr. Ritchie intended that the Act should apply to districts like Lytham, where for so many years voluntary notification had been in existence, and so far as can be judged with satisfactory results. If he had so intended he would not have made it an optional measure for all urban and rural districts (London excepted). It has been urged as a necessity for adopting the Act for Lytham that one of the medical practitioners resident in the town has refused to give the required notification, but I am distlnctly informed by the doctor in question that such is not the case, and that he has not had anything to notify. The adoption of the compulsory Act might easily be the cause of mischief, *as it is not at all unlikely that some persons might be unwilling to call in medical aid, and they might try to hide anything of an infectious character, and plead ignorance rather than incur the risk of publicity. Such instances I am told frequently occur in other districts where the Act is in force. And the Act, as I read it, does not compel persons to call in a doctor.* Further, it would be detrimental to the interest of the town (as a health resort) to give unnecessary publicity to every case of infectious disease which might occur. I can truly say that everything which the Act requires in the way of precautionary measures is in my opinion quite as effectually carried out under the present system as it would be under the compulsory Act. If persons come here recovering from infectious diseases and inadvertently neglect to notify the fact, the adoption of the compulsory Act will not remedy the evil. I am able to speak without hesitation of the care and attention which lodging-house keepers in general give to this very important subject, and also of their refusal to admit into their houses any visitors who have, to their knowledge, recently suffered from infectious complaints, without first consulting their medical adviser. These are some of the prominent reasons which lead me to suggest that, for the present, at any rate the proposed compulsory notification Act, should not be put in force in Lytham."

The Act is imperfect. It is framed in the interest of the public, but one clause is wanted, viz., "that in every case of disease included in this Act, a registered medical practitioner should be consulted." Primary notification to the practitioner would be an effective way of dealing with primary cases.

ASEPTICISM *VERSUS* ANTISEPTICISM.

We publish this month two very important papers, one by Professor Lister, detailing a new departure in the fabrics associated with his name; the other by Dr. Bantock, impugning the very ground on which Listerism stands. The paper by Professor Lister is worthy of perusal, though it is perhaps more interesting to the manufacturing chemists than to the practitioner. A new fabric of this kind means increased outlay for hospitals and for private practitioners, and a large sum of money has been spent already on vapourisers, carbolic gauze, carbolic lotions, carbolised tow, etc. We may presume that all these agents are now valueless. The fashion has changed. Salembroth gauze, etc., have had their brief day. Whether the new dressing will sustain its reputation is a matter of doubt; but whether or not the antiseptic dressing holds its ground, Lister will always have the credit and honour of being the introducer of a system which has for its basis cleanliness, and whether this is secured by cold water or chemical contrivance, the end in view is attained. It is a matter of old history now that the gravest operations can be performed, and the best results obtained by the use of plain water. It is also a matter of old history that results equal to those obtained by the most elaborate contrivances of the antiseptic system have been secured in midwifery practice by the use of cold water. We have in former articles given chapter and verse to this assertion. This means that cleanliness is all essential, and that the aseptic state may be brought about without chemical means. We have passed the stage of intolerance, and now to doubt Lister is not looked upon as the unpardonable sin. It is lamentable to think that in a science like medicine we should have a reign of dogmatism, and that blind, unreasoning faith should be demanded of members of a liberal profession.

"THE INVASION OF THE *MASSEUR*."

Under this heading, *The Medical Record*, New York, has a very pithy article, from which we make the following extract: "We must beg our readers to keep a close eye upon the *masseur*. He is bearing down upon unhinged humanity with a steady and relentless stride. He develops in the midst of us; he sails over from Germany and England to us; while, if there are any graduates of Heilgymnastik still left in Denmark, Sweden, or Norway, we should like to know it; for it has appeared to us, after some busy morning, that they have all called. Truly, the *masseur* is among us. He is a man of great resources. As his fraternity increases, he does not lose heart, or complain of competition, or seek protection from the State—he simply enlarges his field. In olden times the rubbing of a stiff knee with officinal linimentum saponis was the centre and circumference of massage. Soon, however, we learned how soothing was the emollient and theobromated hand upon the hyperæsthetic skin and diseased muscle. The *masseur* became firmly established as the resourceful prop of hysteria and unfailing staff of morbid locomotion. But then the sinewy and insidious hand began to gather adventitious aids, and seek new worlds to conquer. Having organised its movements into a company of Gallic polysyllables, so that its manœuvres of *tapotiment* and *pétrissage* and *effleurage* should not be mistaken for plain, every-day slap-slap, jab-jab, and thump-thump, it proceeded to attack all the several diseases and organs of the body. Adipose tissue in excess was made to disappear, while glandular tissue, if mammary, was rubbed to make it grow. Massage has now applied itself to diseases of the eye, and granular lids are, *quoad* the granulations, artistically rubbed off; it has invaded the mouth and throat, reducing hypertrophied tonsils, opening the Eustachean tubes, and curing catarrh and deafness."

BIRMINGHAM TO THE FRONT.

Birmingham is known to be a progressive town. Its practitioners have acquired some of the spirit, and they are now tackling with energy the abuse of medical charity. They have appointed a committee to devise some means by which this abuse may be remedied. A report has been issued, and a number of propositions boldly stated: "(*a*) That the original purpose of our medical charities has been widely departed from. (*b*) That as a result of this departure the demands made upon them are greater than they can adequately meet, and are increasing from year to year. (*c*) That a constantly increasing proportion of the community depends upon charitable medical relief in times of sickness, rather than on providence and self-help, and that this is unjust to the subscribing public, injurious to the recipients themselves, and an imposition upon the medical profession. (*d*) That in order to bring about a better state of things the voluntary hospital system needs to be re-organised, so that, on the one hand, it may work harmoniously with and supplement the Poor-law system; and on the other hand, it may encourage, and not hinder, as it now does, the development of provident institutions for the medical treatment of the industrial classes." Another meeting was held on November 30th. We are obliged to hold over the account of the proceedings.

THE BRITISH MEDICAL ASSOCIATION.

There are rumours that some of those who are dissatisfied with the British Medical Association management have resigned in a body, and we presume that in this way they are manifesting their displeasure at the way their complaints were received at the Leeds meeting. The effect on the Association of the resignation of 500 members, however honoured, must in the nature of events be *nil*, because it is too late in the day to expect a republican institution like the British Medical Association to pay any regard to explosions of this nature. The profession in American divided over the Congress. The men who thought they were leaders could not rule, so tried to ruin, the result being that the malcontents have ever since suffered themselves. We trust this object lesson from medical history will not be without its value.

THE TENTH INTERNANIONAL MEDICAL CONGRESS.

Professor Rudolph Virchow has been appointed president of the next International Medical Congress. The general rules and regulations of this Congress have been sent out by the general secretary, Dr. Lassar, of Berlin. These relate to the organisation of the Congress, and resemble the regulations that have always been issued regarding the meetings. (1) The Congress is to open on Monday, August 4th, 1890, at Berlin, and to close on Sunday, August 10th. (2) The Congress is to consist of regular, licensed (*approbirten*) physicians, who have enrolled themselves as members and obtained members' cards. Other learned men interested in the work of the Congress can become associate members. The cost of membership will be twenty marks. (3) The objects of the Congress are exclusively scientific. (4) The work of the Congress will be done in eighteen sections. (7) The general sessions will be devoted to (*a*) the measures regarding the general regulation of the Congress, and (*b*) addresses and communications of general interest. (8) Notices of papers to be read, and abstracts of them, must be sent to the Organisation Committee before July, 1890. (9) Written copies of the articles to be read must be sent to the secretary of the section before the conclusion of the session. (11) The official languages will be German, French, and English. (12) Communications must be limited to twenty minutes, and discussions to ten minutes. (13) The sessions will be regulated by generally received parliamentary rules. (14) Students of medicine, and others interested in the work of the sessions, can be admitted by securing invitations. (15) Communications, or questions regarding the work of the special sections, should be addressed to the president of the section. Other communications should be addressed to the general secretary, Dr. Lassar, Berlin, N.W., Karlstrasse 19.

New Remedies.

Casearia Esculenta.—This drug has been introduced to the notice of the medical profession by Dr. P. S. Mootooswamy, F.L.S. (Tangore), who believes it to be of considerable value in the treatment of chronic enlargement of the liver, also for hepatic obstruction and piles.

Botanical Characters.—*Casearia esculenta* is a large shrub or small tree, having alternate oblong leaves with entire margins and smooth surface, axillary, greenish, yellow apetalous flowers, which have the stamens and nectaries united at the base. It belongs to the natural order Samydaceæ, and is a native of the Circar Mountains, the Ghauts of Travancore, Varoosa-puthee, and other parts of the Tanjòre district.

Description.—The root is the part employed in medicine by the Hindus, and is regularly sold in the medical bazaars of the district. In the Tamil language it is called "kadalashingi" and "kadaloorangi," but in Telugu it is named "gundu-gunguru." Unfortunately, there is another drug bearing the same name of kadaloorangi, belonging to the Malvaceæ. It is bitter and astringent, and mucilaginous, and is the product of *Kydia calycina*.

The root of *Casearia esculenta* varies in size, the average being about an inch in diameter. Externally it is of a bright yellow colour, and the superficial layer easily exfoliates in pieces as thin as tissue paper. Internally the bark is reddish brown. The wood of the root is marked with concentric zones, varying in number according to the age of the tree, and is light brown in colour. When powdered in a mortar the broken pieces of bark adhere together by the fine long silky liber cells, and give the powder a peculiar cobweb-like appearance, which, with the bright yellow colour of the outer bark, enables it to be easily recognised. It would be interesting to know whether the ancient doctrine of signatures suggested the use of this yellowish root in liver diseases.

Chemistry.—The root has been analysed by Mr. David Hooper, who found it to contain 3 per cent. of neutral resins, partly soluble in spirits of wine, and soluble in ether; tannin about 10 per cent., giving a greenish colour with ferric salts, and resembling rhatania tannic acid in the composition of its lead salt, and in forming a soluble crystalline product when boiled with dilute acid; a cathartic acid, soluble in water, and agreeing in chemical and physiological tests with the cathartic acid of senna. The root also contains a little starch, and 4.8 per cent. of mineral matter.

Properties and Uses.—It is a gentle aperient, notwithstanding the tannin present, and is considered by some Vytians to be an alterative in skin diseases, especially in the disease bearing the Tamil name of "padurthamaray," which affects the lower part of the abdomen and extends around the back, and apparently has its origin in disturbance of the hepatic function. For this complaint the bark, ground with water, is applied locally. Dr. Mootooswamy has long know the root to act as a specific in diabetes when administered in powder or decoction, but it is especially as a valuable remedy for chronic enlargement of the liver, for hepatic obstruction, and for piles, that this new remedy is recommended.

Preparations and Doses.—The dose of the powdered root is two or three drachms, with one-quarter of its weight of sugar, twice a day. This is, however, rather a bulky dose, and the decoction would be generally preferred. This is made according to the following formula:

℞ Root bark of casearia ..... ℥ ij.
Cinnamon bark ..... ℥ ij.
Aniseed ..... ℥ ij.
Water ..... ℥ x.

To be boiled down to three ounces. Dose, an ounce and a half twice a day. The extract and syrup are now largely used in Bombay; the extract is made by exhausting the powdered root with water and evaporating to the consistence of soft extract, of which the dose is twenty grains. The syrup is made from the extract, twenty grains of the extract being contained in two drachms of the syrup, which is taken for a dose.

Periscope.

I.—GLEANINGS IN MEDICINE.

By W. B. Kesteven, M.D.

Thiol, a Rival of Ichthyol (*Medical Record*, New York, October 16th).—Ichthyol has found a rival in thiol, a new product of chemical synthesis, obtained by artificially sulphuretting unsaturated hydro-carbons, and charging these with 10 per cent. of sulphur (The Provincial Medical Journal). Chemical and therapeutical researches prove its exact identity with ichthyol. Thiol consists of a brown fluid of the consistency of syrup; it is completely soluble in water, is totally inodorous, and has therefore a decided advantage over ichthyol. There exists also a dry thiol, which has two and a half times the strength of fluid thiol, otherwise having the same properties as the latter. Thiol is used like ichthyol in the following diseases: Acne, acute and chronic rheumatic arthritis, other rheumatic affections, contusions, decubitus, eczema, erysipelas, neuralgia, ischia, leprosy, frost-bites, prurigo, pruritus, ulcus cruris, burns, and scalds. On the initiative of Schweninger, thiol was tried at the Charité Clinic of Berlin, and Dr. Reeps reports on these trials in a very favourable light, as does also Dr. Buzzi, whose opinion is based on an even more extended clinical experience. Dr. Reeps states that it may safely be concluded that thiol, externally applied in skin diseases, has positively the same effect as ichthyol. As their effect in these instances is identical, it may also be assumed that thiol will prove equally efficacious in other diseases where ichthyol has been employed. Reeps has taken internal doses up to two and a half grammes without discomfort or disturbance of the stomach; and he believes, therefore, that it is comparatively harmless. It has been asserted lately that this is not the case with ichthyol, but he ascribes the adverse physiological effects of ichthyol to its obnoxious taste and odour, and these are entirely eliminated in thiol. He does not consider there is any further doubt that thiol and ichthyol are two exactly identical substances, and that thiol will serve to replace ichthyol when the natural sources of the latter remedy become exhausted; even now the discovery may be recognised as a great boon, which makes us independent of nature's supply of this valuable remedy.

Reduction of Hernia by Coughing (*Annales d' Orthopédie*, 15th June, 1889).—At the Medical Society, Paris, Dr. Vandenabeele reported several cases in which he has succeeded in reducing hernia by availing himself of the patient's cough. He takes the hernial tumour in his hand, and requires the patient to cough. Thirteen cases were relieved in this manner, which Dr. Vandenabeele considers easier and more convenient than taxis. The cough dilates the inguinal ring by pressure of the gaseous contents of the intestines.

Notes on the Value of Hyoscine as a Sedative. By Walter S. Coleman, M.B., and James Taylor, M.D. (*Lancet*, October 12th, 1889).—The preparation used in the cases under notice was 1 in 500 of the hydrobromate of hyoscine in distilled water. This strength is a convenient one, five minims being equivalent to a dose of $\frac{1}{100}$th of a grain of the salt. [Care should be taken to obtain the hydrobromate of hyoscine from a reliable chemist. It is perhaps superfluous to say that it must not be confounded with hyoscyamine.] The cases in which it has been used are: (1) Mental excitement, with epileptiform convulsions. The injection of $\frac{1}{200}$ gr. at once quieted the patient; the dose, however, required to be increased to $\frac{1}{75}$ gr. No bad effects followed. (2) A case of tumour of the cerebellum, with maniacal excitement. The injection of $\frac{1}{75}$ gr, completely allayed the excitement and produced sleep. (3) General paralysis, with excitement. Cases 4, 5, 6, 7, 8, were epileptic, with mania. (9) Hysterical contraction of the arm, with violent excitement. In another instance, hyoscine was given as a substitute for morphia, that drug being inadmissible. Occasionally, unpleasant effects followed the use of the hyoscine—*e.g.*, hallucination, dimness of sight, excessive dryness of the mouth; but the drug was always found to be a certain, rapid, and effective sedative in cases of violence and excitement. In violent cases, $\frac{1}{100}$ gr. may be injected; if no effect is produced in half an hour, a second dose of $\frac{1}{200}$ may be given. In chronic cases, $\frac{1}{300}$ is a safe dose. When given by the mouth, the dose should be doubled.

New Hypnotics (*The Medical Record*, New York, October 16th).—At a meeting of the New York State Medical Association, September, 1889, Dr. William H. Flint reviewed the literature of the new hypnotics, and then gave conclusions based principally on his own experience with them. He had used sulphonal most, as being the most efficient or desirable of the new hypnotics. Its physiological action had not yet been thoroughly established. As a hypnotic it was valuable in some forms of insanity, neurasthenia, acute sthenic febrile diseases, opium

habit, gastric irritability, and some cases of anæmia. In gastralgia, gastritis, and some other conditions, it was contra-indicated. Toxic symptoms were not likely to manifest themselves unless the dose exceeded thirty grains in the adult. A large dose caused fatigue, depression, vertigo, tinnitus aurium, and œdema of the eyelids; it might cause even collapse. It was best administered by the mouth, with hot beverages or liquid food, an hour and a half before the desired action. He had not yet seen a sulphonal habit. There had been about 80 per cent. of successes in his cases. He had administered amylene hydrate in thirty-eight cases of insomnia, in various diseases, obtaining hypnotic effects in over 70 per cent. Its physiological effects were similar to those of alcohol. Its odour was disagreeable. It should not be given in gastric disease, because slightly irritating. He had recently used paraldehyde in thirty-five adult cases for insomnia, with successful results in 72 per cent. It was not irritating to the stomach. If too large doses were given a long time, a condition resembling chronic alcoholism might develop. It was best given in soft capsules. He spoke less favourably of the other hypnotics.

Antipyrin in Diabetes (*The Medical Record*, New York, October 16th).—Drs. Gley and Germain Sée report a number of cases of artificial glycosuria in dogs, in which the good effects of antipyrin in this affection were well illustrated. To a dog passing thirteen grammes of sugar a day, one gramme of antipyrin per diem was given for eight days, at the end of which time the amount of sugar had fallen to eleven grammes. At another time, the quantity of sugar was reduced by the same means from about ten to less than six grammes. Dr. Sée has also employed the drug in the treatment of glycosuria in the human subject with good results. Lépine and Porteret have shown that antipyrin has the effect of retarding the transformation of glycogen in the liver and muscles into glucose. M. Huchard has previously related several cases of polyuria and glycosuria, in which the exhibition of antipyrin was followed by good results. The latter author believes that this drug has a special utility in bulbar neuroses, among which he classes diabetes, polyuria, and exophthalmic goître.—*Revue Générale de Clinique et de Thérapeutique.*

The Value of Oxygen combined with Nitrogen Monoxide in the Treatment of Pulmonary and other Troubles. By Dr. E. C. Titus, M.D., of New York (*Medical Record*, New York, October 5th).—In the *Medical Record* of July 6th there appeared a very able article by Professor W. Gilman Thompson, showing a series of experiments with oxygen upon animals, and the conclusions arrived at as a result of those experiments. The conclusions were in the main such as I have demonstrated repeatedly by clinical experience. In the treatment of pulmonary complaints the tendency at the present time is toward local medication. This arises principally from the general acceptance of the germ theory, which teaches in the main that diseases originate from micro-organisms, and the belief that from this it must follow, as a necessity, that these micro-organisms must be destroyed or rendered harmless to organized tissues, either as a means of cure, or as a prophylaxis to such a disease. For these reasons attention has been directed more particularly to the study of means whereby antiseptics or germicides may be made to reach disease-germs in the lungs more directly and safely than has hitherto been known.

If tuberculosis depend upon the presence of infectious organisms in the tissues, then certainly the most rational mode of treatment in phthisis must include the administration of antiseptic agents. The most powerful antiseptic known to science is oxygen, for in an atmosphere of oxygen it is impossible for disease-germs to exist.

It has been found by clinical experience that oxygen is less irritating and more readily absorbed when combined with a certain equivalent of nitrogen monoxide. The proportions that I have found most valuable are two parts pure oxygen and one part nitrogen. In order to obtain good results, it is of the utmost importance that these gases should be absolutely pure. Pure oxygen I believe to be too powerful an oxidizing agent when used alone; especially when there exists inflammation in the air-passages. In cases of poisoning from hydrogen gas, however, it is better to use it undiluted. Nitrogen monoxide is valuable as a modifier of pure oxygen, and has a soothing effect upon the nervous system. It renders the oxygen with which it mingles more assimilable, and hence more promptly available in the general system. The discussion at the New York Academy of Medicine, following the reading of Professor Thompson's paper, was interesting in showing how generally this agent is now being used by the most advanced men in the profession. The method of administration is important. The patient should be instructed to expel as completely as possible the air from the lungs, and then inhale deeply, and after fully inflating the lungs it should be held as long as possible before being expired through the nose; there should be an interval of two minutes between each inhalation; this method is applicable to the treatment of phthisis and anæmia. In pneumonia it should be administered continuously from three to five minutes, and as frequently as the urgency of the case demands.

Athrepsia: a Wasting Disease of Childhood (*The Medical Record*, New York, October 16th).—In the *Revue mensuelle des Maladies de l' Enfance* Dr. Legournet has published an article on athrepsia, a *résumé* of which appears in the *Archives of Pediatrics*. Athrepsia is a morbid condition of infants which is characterised by disorders of digestion and nutrition, and results in defective or improper alimentation. The most striking symptom in the physiognomy of an athrepsic patient is emaciation. The child loses weight rapidly, and may lose as much as twenty or thirty grammes daily. Parrot divided the disease into several periods, and recognised several degrees in the gravity of the disease. It frequently begins at the end of the first week of life, the process of denutrition or innutrition being consecutive to that which existed at birth. If it is remembered that for the first few days after birth an infant normally loses thirty or forty grammes daily, even with a good nurse, this loss being rapidly made up in the succeeding period, it is easy to understand how great the loss in vitality must be to infants who lose much more than that, and then fail to gain correspondingly in the succeeding days. Such children may live from three to six weeks, being apparently at death's door all the time, and becoming more and more feeble and emaciated. In the grave form of athrepsia one may distinguish three periods—one which is marked by the phenomena of indigestion and by green diarrhœa; a second which is marked by vomiting, muguet, erythema of the scrotum, the thighs, and the anal region, emaciation, and chilliness. If suitable food be given, it is possible to restore the child even from such unfavourable conditions. The third period is that of cachexia, and is followed by death from exhaustion, or from complications which intervene. The rapid form of athrepsia is the most common one, the child succumbing in three to six weeks. In the slow form the child may even gain weight in spite of bad hygiene, and may reach the age of several months, dying without complications. The author distinguishes an acute athrepsia from the rapid variety by the fact that in the latter the infant has never been able to profit by the food which was given him, while the other made irregular progress, the regimen being tolerated for awhile, and then giving rise to gastro-intestinal disorder. The latter will die unless suitable dietetic changes are made; the former may be able to exist without much change of diet if he survives the gastro-intestinal attack. But a child who survives this bad usage is very likely to show the effects of it in his physiognomy, his bearing, his functions; and his nutrition. Such children become rachitic, have pulmonary or other serious troubles, their teeth appear late and are badly developed, and the individuals themselves usually die young. The mortality from this disease is very great. In the author's district, which includes a population of four thousand, about one-third of the deaths under one year of age, and one-seventeenth of the total number of deaths, were from this cause during a given period. All the infants were bottle-fed. The statistics of the entire city of Paris were even more astonishing, for there nearly two-thirds of the infants are bottle-fed. [An American physician is reported to have said that if Herod had only known of the long-tubed feeding bottles, it would have saved him some trouble.—*Reporter.*]

Solanum Carolinense (Horse-nettle). By George Foy, F.R.C.S. (*The Medical Press*, October 15th).—The claims of this plant to be considered a valuable therapeutic agent in convulsive affections have been brought forward by Dr. J. L. Napier, of South Carolina. The preparation used was a tincture prepared from the fruit of the plant. Dr. Napier has found it to be of great benefit in epilepsy, where bromides had failed. The dose of the tincture of the berries is from ten drops to a drachm, and should be pushed until drowsiness is produced.

The Diagnosis of Leprosy. By Dr. P. A. Morrow, of New York (*New York Medical Journal*, October 26th, 1889.)—Little was said in the text-books about the diagnosis of the disease, perhaps because few writers had been personally familiar with it. In the latter stages the diagnosis was not difficult, but in its inception it was often doubtful. In the examination of the suspects at Honolulu a large number were remanded for further developments, and it should be borne in mind that this was not owing to any lack of skill on the part of the physicians. Many of the initial symptoms were quite indeterminate, and might be referred either to leprosy or to other diseases. The affection was most likely to be confounded with erythematous diseases, with lupus, and with certain affections of the nervous system, while many parasitic diseases had lesions similar to those met with in this disease. Two main forms of leprosy were recognised—the tubercular and the anæsthetic. In one there was a determination of the process to the integumentary tissues, and in the other to the nervous system. In tubercular leprosy the prodromal symptoms had little value, and the same might be present in syphilis and other diseases. In this form the

presence or absence of anæsthesia was of no diagnostic value whatever. The eruption was not at all pathognomonic. The macules which first appeared were round, oval, or irregular, of a bright or sometimes dark-red colour, fading on pressure. As a rule, they were not infiltrated, and might disappear without a trace, or they might leave a yellowish spot. Sometimes they might present a picture similar to that of erythema multiform. After a time these macules became persistent, and then there was a tendency to the formation of tubercles; but the latter might develop in isolated spots, quite apart from the large erythematous areas. In its origin the disease resembled syphilis in the long period of incubation and the successive crops of the eruption. The syphilitic roseola corresponded to the leprous erythema; the mucous membranes were affected in each, although the throat was not affected in leprosy. There was more infiltration of the skin, especially in the face, in leprosy, and leontiasis was more often seen, as well as the breaking down of the osseous framework of the nose. Sometimes the tubercles of this disease resembled very much those of lupus. Sarcoma had been confounded with the disease, but when the fungoid state was reached and the tumour suppurated the distinction was easily made. The disease had also been mistaken for acne, sycosis, lichen planus, erythema modosum, molluscum fibrosum, and dermatitis medicamentosa. The *Bacillus leprœ* was invariably found in the tissues and stamped the disease when such examination could be made.

The anæsthetic form of the disease presented a greater variety and complexity of symptoms. While the demonstration of the bacillus was rarely practicable, yet the invariable presence of anæsthesia had almost a pathognomonic value. The nerves most frequently affected were the ulnar, the peroneal, and the third and seventh pairs. There might be wrist-drop and a peculiar claw-like contraction of the fingers. Since the pathological lesion was a multiple neuritis, it was not surprising that there were many diseases of the central nervous system which resembled leprosy. The atrophy and degenerative changes might be limited to the muscles of the hand and forearm, and might present a perfect picture of the lesions of progressive muscular atrophy. They were distinguished by the presence or absence of sensory disorders. The disease most difficult to distinguish from it was syringomyelia. This disease had formerly been considered to be very rare, and to be met with only *post-mortem*, but of late a number of cases had been reported. Its main symptoms were sensory disorders and trophic changes.

On Gunshot Wounds of the Abdomen, with especial reference to Wounds of the Intestines. By Lewis A. Stimson, M.D.—Until within a period relatively short, a discussion of the subject of gunshot wounds in a society of surgeons in civil life would have had an interest almost exclusively academical, and, apart from theoretical considerations and analogy, would have been based in great part upon experience gained at the edge of the battle-field and in the military hospital. But the times have changed, and now, to paraphrase a well-known quotation, Peace hath her military surgery no less renowned than war; and in some varieties of gunshot wounds, such as those of the trunk and head, the office of the military surgeon has diminished, while that of his brother in civil life shows the budding promise of an important development. The reason is not far to seek. On the one side, military fire-arms now discharge their fire-arms with such velocity that the wounds they inflict upon the viscera are very severe, and often beyond hope; while, on the other hand, the possession of parlour rifles and of pistols of small and medium calibre in all classes of the community has become very common, and the injuries inflicted by such, either accidentally or with hostile intent, have correspondingly multiplied. As an indication of this frequency of occurrence of such injuries, I may say that I can recall, without search of the records, twenty cases of serious bullet wounds personally treated by me during the twelve months last past; of these, seven were accidental, three were inflicted with suicidal, and ten with murderous intent. So long, therefore, as pistols are openly sold at prices that place them within the reach of almost every half-grown or adult member of the community; so long as love, anger and despair, greed and want, are strong motives of action; so long as youth is heedless; and so long as the idiot who thinks it is not loaded goes free in the midst of us—so long will gunshot wounds demand our care and attention, and deserve our thoughtful study.

All varieties of these injuries have shared in the benefits conferred by modern improvements in the care of wounds and in the stimulus to effort created thereby; but, while in wounds of the extremities the gain has been in the preservation of limbs that would otherwise have been lost, in gunshot wounds of the abdomen the interest is infinitely greater, for the issue is of life or death, and it is beyond dispute that many lives have been already saved by operation during the last five years which would certainly have been lost under the methods of treatment which had previously prevailed. It has been fully established that formal laparotomy, undertaken to discover and repair gunshot wounds of the intestines, may save lives that are in imminent peril; and that, consequently, under certain circumstances, it is a proper and justifiable operation. But from this to the position that in every gunshot wound of the abdomen that is probably perforating, a laparotomy should be performed, is a long step. It is not enough to have shown that some patients have survived laparotomy; it is not enough to have shown that those who have died without operation could have been saved only by one; it is not enough to have shown that laparotomy for other morbid conditions is daily done with a large measure of success and safety. It must also be shown thst it saves a larger proportion of wounded patients than other methods save; and, even if this is done, it must still be ascertained whether we cannot discriminate between the different injuries, and recognise those in which it is wiser to abstain.

The operation of freely opening the abdominal cavity to search for and repair gunshot wounds of the intestines is not a new one; it does not even belong solely to the period of antiseptic surgery, but it was performed, and successfully performed, more than fifty years ago. The principles which lie at the foundation have, of course, been apparent since such wounds were first inflicted. No demonstration was needed to show the desirability of closing the wound in the intestine, or the advantage of a free opening in the abdominal wall if sutures were to be applied, or if the wound was to be sought; but the fear of making such an opening, or of operating upon the intestines, was so great, and, indeed, so well founded as surgery was then done, that surgeons, with but few exceptions, almost down to the present time, practised and taught abstention, except when the wounded loop of intestine protruded through the opening in the abdominal wall or lay in plain sight beneath it. Under such circumstances they sutured the intestine and returned it, or they promoted the escape of fæces from within the cavity, and sought safety in the establishment of a fæcal fistula. Occasionally, the possibility of advantage in a more active intervention was more or less hesitatingly suggested; and Baudens, in a work published in 1836, reported a case operated upon in 1831, which is not only the first instance of the operation we are considering, but which was also said by the editor of the "Medical and Surgical History of the War of the Rebellion" to be, in 1877, "perhaps the only instance of completely successful enterorrhaphy for shot-wound on record." It is to be remembered that the earlier experience is drawn almost wholly from military surgery, and that the bullets were much larger, and discharged with a much lower initial velocity than at the present time. The wound of the abdominal wall appears usually to have been large enough at least to permit the introduction of the finger, and often to permit spontaneous protrusion of a wounded loop of intestine.

The great majority of these cases are of date subsequent to the publication of the opinions in favour of laparotomy quoted above. In all of them the treatment consisted almost solely in the administration of opium, and in many the parietal wound was washed with some antiseptic solution, and then covered with carbolic or iodoform gauze. Surgeons possessed, practically, all the knowledge of the pathology of abdominal shot-wounds, of the various processes by which death is caused or repair effected, and of the methods of operation upon the intestine which they now have. They knew what was necessary or desirable to be done to increase the chances of recovery, but their hands were stayed by the fear that to do what was necessary or desirable was even more dangerous than to leave it undone. The fear had heretofore been well founded, and operations in which the peritoneal cavity was freely opened deservedly ranked among the most serious. But with generalisation of the antiseptic method came increased security and confidence, and came also a revision of former notion of what was practicable and permissible, and a great increase in the range of operations. The opening of the peritoneal cavity for the relief of disease was done, not only with greatly increased frequency, but also with great success, and it became only a question of time and opportunity when it should be extended to gunshot injuries. The first operation under the new conditions and new ideas was done by Dr. Sévastopoulo, of Constantinople, in October, 1880; but, as it was not published until 1887, it remained without effect upon the opinions and practice of the profession. It was a repetition, and the first repetition if the cases of Nélaton and Pirogoff are excluded, under the protection of antiseptics, of Baudens's operation in 1831.

Swallowing a Toothbrush (*Medical Press*, October 16th).—Dr. Hashimoto relates the case of a woman, æt. forty-nine, who was in the habit of titillating the epiglottis and posterior part of the pharnyx with a toothbrush, which seems to have a holder easily detatched. On one of these occasions she swallowed the brush. About ten months after this occurrence an abscess formed over the region of the stomach, which burst, and allowed the pointed end of the brush so protrude. It seems that the attendant removed about a centimetre of the foreign body and allowed the wound to heal up, with still an uncomfortable feeling about

the stomach. About thirteen years afterwards another swelling and abscess formed in the region of the umbilicus, where the foreign body could be felt. After the abscess discharged, a fistula was formed, through which the brush was extracted, leaving an opening direct into the stomach, from which was emitted odourless gas, while the secretions were acid. In the course of five weeks the fistulous opening healed up. He related another case of a hairdresser, æt. thirty-six, who had a similar misfortune in swallowing his toothbrush, which protruded from the stomach about the sixth day after the accident, but unhappily by some perforation of the peritoneum or absence of adhesion to the outer walls, the patient died three days after its removal.

Billroth on the dangers of Carbolic Acid (*New York Medical Journal*, October 26th.)—The following note by Billroth, of Vienna, has been published; "I have lately seen four cases in which fingers, which had suffered a most insignificant injury, because gangrenous through the un-called-for application of carbolic acid. Carbolic acid is now so much less used in surgery than formerly; we have only gradually become acquainted with its dangers. The acid may not only cause inflammation and gangrene, but also blood-poisoning, and so may even prove fatal. It is useful only in the hands of a skilful surgeon, and ought never to be used without his advice. The best lotion for recent injuries is the ordinary lead lotion, which can be bought at any chemist's. The best antidote in carbolic acid poisoning is soap, which should be taken immediately and repeatedly until all symptoms of poisoning have disappeared."—*Lancet.*

Poisoning by Illuminating Gas—Rational Treatment. By William C. Kloman, M.D., Baltimore (*New York Medical Journal*, October, 1889.)—Modern illuminating gas, the so-called "water gas," is a much more dangerous poison to the human system than the original gas made from coal. Booth ("Encyclopædia of Chemistry") states that illuminating gas made from coal consists, on an average, of light carbureted hydrogen, 57-7; carbonic oxide, 7.7.; hydrogen, 21.2, etc., while the modern gas, on the authority of Professor P. B. Wilson, inspector of gas, etc., contains from 20 to 30 per cent. of carbonic oxide, showing an increase of from 300 to 400 per cent. Now, there is every reason to believe that the carbonic oxide is the actual poisonous constituent of illuminating gas.

The actual nature of poisoning by carbonic oxide is yet a mooted question. Some authorities, such as Claude Bernard, Hoppe-Seyler, and others, believe the symptoms are entirely due to merely a deprivation of oxygen; others, such as Klebs, believe that carbonic oxide has narcotic properties acting on the central nervous system, independent of its power of robbing the blood of oxygen. At any rate, it is established that carbonic oxide has the power of decomposing the oxyhæmoglobin and forming a new compound with the hæmoglobin, combining in the same volumetric proportions and forming a new compound with the hæmoglobin, combining in the same volumetric proportions and forming a new compound which is crystallizable and which can be separated from the blood. This new compound is more stable than oxyhæmoglobin, and is not decomposed by the presence of oxygen. In fact, to the extent of its presence in the blood, it seems to render the absorption of oxygen impossible, and if the entire quantity of oxyhæmoglobin of the blood is replaced by it, life is no longer possible.

On September 4th, 1889, I was called at 6-30 a.m., to see Diana, a coloured girl æt. seventeen years, a domestic in the family of Mr. S. She had recently come to the city from Virginia, and was not familiar with the use of gas. She was shown how to turn off the stop-cock and extinguish the flame. She went to bed at about 10 p.m., and was found insensible in her bed at 5 a.m., or soon after. The room door and window were both closed and the atmosphere filled with the smell of escaping gas. The stop-cock was found partially turned off. Before my arrival she was moved to the adjoining bath-room, where the window was open. I found her lying upon the floor; her limbs were cold and relaxed; I could feel no pulse at the wrist; there was no sign of life except respiration, which was shallow and stertorous. The eyes were partly open, staring and fixed; the conjunctivæ were intensely congested; the pupils moderately dilated and insensible to light; the eyes were also insensible to touch. She was in a profound coma. I at once dissolved one of Sharp & Dohme's hypodermic tablets of nitroglycerin, one fiftieth of a grain, in my hypodermic syringe, and injected the solution into the proper arm. Her body was directed to be covered with blankets. In about two minutes I could feel pulsation at the wrist, and in five minutes her pulse was full and strong. *Pari passu*, the respiratory movement deepened and her limbs began to grow warm. In about fifteen minutes, while yet unconscious, she showed signs of vomiting; I turned her on her side, and she vomited some mucus and partly digested food containing some pieces of tomato. Soon after this she became partly conscious, and reaction being thoroughly established, I wrote a prescription for æther, sulph., ℥ss.; elix. ammon. valer., ℥jss., and directed that during my absence a teaspoonful diluted with water be administered every second hour. I returned to see her in about three hours, when, to my surprise, Diana walked into the parlour. She told me she was all right except for a slight headache. She also said that she had been constipated for several days, for which I ordered her a purgative. Beyond this she had no medication. Her headache continued for two or three days, but did not interfere with the performance of her duties.

A noteworthy point in this history is the length of time during which the patient was exposed to the inhalation of the gas—a period of not less than seven hours. I was doubtful of this until her recovery, when I questioned her, but found that she recollected nothing from the time she went to bed until she regained consciousness in the morning. It is not possible for me to state how much percentage of gas was in the atmosphere she breathed during the night, for the stop-cock was entirely turned off at once and the door and window of the room were opened before I came. In this connection, however, we must remember that there is a great difference in the susceptibility of different persons to its poisonous influence. Yet, whatever the amount of gas respired, it was evidently enough to render her deeply comatose and very nearly deprive her of life.

II.—SELECTIONS FROM CONTINENTAL MEDICAL JOURNALS.

By G. F. Cadogan-Masterman, M.D.

Diabetic Coma. By Dr. Gaston Lyon (*Revista de Ciencias Médicas*)—*continued from p.* 696.—This immunity in the dog is partly physiological, partly pathological. A flesh-eater has, obviously, more of the materials at hand for forming ammonia than an animal confined to a vegetable diet; and when this facility in production is stimulated by the necessity for neutralizing and, so, safely carrying off a poisonous acid, its formation may be correspondingly rapid without any very great strain—for a time at least—upon the system.

But when this excretion of ammonia—which may be formed *pari passu* with the acid it has to combine with—cannot be provided for, the acid forms a salt at the expense of the soda existing in the blood, and at once deprives that fluid of its most important respiratory base. "The blood acts as an absorber and carrier of carbonic acid solely by the presence therein of the alkaline tribasic-phosphate of soda, which not only absorbs carbonic acid better than a solution of the carbonate, but gives up the whole of it on exposure to the air" ("Gregory Chem.," vol. ii.). In a fluid containing free acid this salt cannot exist, and a phosphate forms containing two equivalents of combined water which is not a solvent of carbonic acid. So we have here one explanation of the coma: it is due, but only indirectly, to the presence of abnormal acids (or in abnormal quantities) in the blood, either diacetic, oxybuteric, crotonic, or formic—all of these have been found—or some mineral acid introduced artificially; but neither of these can, *per se*, produce coma, *that* is due to the accumulation in the veins, cells or lymph of the brain, of carbonic acid, from the inability of the alkali-robbed blood to carry it off to the lungs for expulsion.

And this, too, affords an explanation of the dyspnœa of diabetics, or, not to neglect the factor of the weakened heart, at least of great part of it. This dyspnœa is one of the chief evidences of the increased gravity of the case, and is often as distressing as in the severest cases of asthma. "The patient seems as if he were thirsting for air, and makes prodigious efforts both in filling and—in this respect differing from the asthmatic—in emptying the chest, in strange contrast to his aspect of helpless exhaustion" (Knumaul). And there is no orthopnœa, in this, again, differing from the asthmatic, and, which lends additional support to the idea that the trouble is not due so much to difficulty in the circulation of the blood, as to absence of the power to carry carbonic acid therein.

When the disease has reached the stage of coma the symptoms are: (1) The odour of the breath and of the urine; (2) respiratory difficulties; (3) gastro-intestinal disorders; (4) nervous disturbances. The odour of the breath, as has been observed, may be noticed in the earlier stages of diabetes before coma is threatened, but as this latter stage is approaching, or has been reached, it is much more marked, may sometimes even pervade the atmosphere of the house.

In the urine the odour may usually be detected, but is not so marked. And this secretion is generally lessened in quantity, contains about the normal amount of urea, less sugar, and frequently albumen; and perchloride of iron pretty constantly gives the Burgundy-wine colour characteristic of diacetic acid.

The dyspnœa is highly symptomatic, although that due to albuminuria somewhat resembles it; but it has one feature, the Cheyne-Stokes rhythmn, which is absent in the latter.

The gastro-intestinal troubles are always marked—often severe:

nausea, sometimes actual vomiting, abdominal pain and diarrhœa. From the profound disturbance of the hepatic functions the motions are occasionally as frequent, liquid and colourless, as in cholera. And the pain may be so great as to suggest peritonitis did not the always lowered temperature eliminate this error.

The effects on the brain are two-fold. At first there is often evidence of stimulation or irritation; there is unusual gaiety, exhilaration, sometimes incoherence in language, even maniacal delirium; or, perhaps, only extreme restlessness. But depression soon follows, the patient becomes passively indolent, utterly apathetic, vacant and somnolent. And this at length passes into unmistakable coma, the border-land of death, with but a step to overpass it.

But the end may be reached during any one of these stages. The dyspnœa, the diarrhœa, the exhausted heart may precipitate the death of the sufferer. When coma is fully developed the patient cannot be aroused, but lies helplessly supine, the face pale, speech lost, with no paralysis, but invariably with a greatly-lowered temperature. Of these symptoms three are pathognomonic: the characteristic dyspnœa, the odour of the breath, and the subnormal temperature. In conjunction they distinguish diabetic coma, with sufficient clearness, from any other which a doctor who had not previously seen the case might confuse with it. For instance, in apoplectic coma there is the accompanying hemiplegia; no sugar, no acetone in the urine, and the temperature is usually raised.

In the alcoholic there is the red, swollen face, natural or raised temperature, and no sugar nor acetone odour of breath. In the saturnine there is the blue line on the gums and, again, neither sugar nor acetone; and in these three cases there is no dyspnœa present.

Cases of poisoning by opium present more similarity to diabetic coma, especially as the urine then often contains sugar, and any meconic acid passing the kidneys would give a red reaction with perchloride of iron; but the contracted pupils, the odour of the breath, and the character of the respiration, distinguish them.

The most difficult to differentiate is uræmic coma, for any of the little water passed would contain albumen, and there is dyspnœa as well; but it is less profound, and the Cheyne-Stokes sequence is absent, while convulsions are usually present.

This new theory has necessarily suggested a change in treatment to the extent of the free use of carbonate of soda, both by the mouth and by intervenous injections in conjunction with common salt, but up to the present time the results have been most unsatisfactory.

Treatment of Tonsillitis. Dr. Haberkom (*Centralb. f. Chir.*).—Chlorate of potash alone, or in combination with hydrochloric acid in the form of gargles, or taken internally, is so often disappointing in the treatment of enlarged tonsils that better means are desirable. The belief that the disease is of parasitic origin has led to the use of such dangerous germicides as carbolic acid and bichloride of mercury; whilst the harmless, if not very active boracic acid has pretty well displaced the chlorate in domestic practice. Then salicylic acid was used, and with excellent results when applied judiciously. In the form of gargle it is least satisfactory, and often fails to reach the affected surface; as spray it is better, but to use that effectually trained hands are needed.

The best and simplest mode is to apply the powdered acid directly by means of a rather large camel's hair pencil, which may be slightly moistened. In this way it is brought directly in contact with the diseased surface, and but few applications are necessary. And it may be used with very young children after a little coaxing.

When the tonsils are covered with a thick mucous coating—which may be diphtheritic—it is necessary to previously remove it, and the following liquid, to be also applied with a brush, acts extremely well:

Pepsine	30 grains.
Dilute hydrochloric acid	ʒ i.
Water	ʒ v.
Glycerine	ʒ iv.

The coating is quickly dissolved (digested) in this solution.

Besides applying the acid locally, it is advisable to give it internally at the same time, thus:

Salicylic acid	30 grains.
Mucilage of Acacia	℥ i.
Simple Syrup	℥ ss.
Water	℥ ivss.

Mix.: A tablespoonful every two hours.

In the more chronic forms it is well to pencil the tonsils over with:

Tannin	15 grains.
Tincture of Iodine	2 drops.
Glycerine	ʒ v.
Water	ʒ oi.

or it may be used as a gargle.

For the prompt dispersal of threatened quinsy, apply with a brush three times a day the following solution:

Tannin	15 grains.
Tincture of Iodine	3 drops.
Carbolic acid	ʒ ss.
Glycerine	ʒ v.
Water	ʒ iiss.

Bromidrosis.—From experiments which have been carried out on an extensive scale in the Prussian army, it is found that this disagreeable affection can be very successfully treated by the application of a 5 per cent. solution of chromic acid. The feet should be thoroughly washed and dried, and then lightly brushed over with the solution. The application may need to be repeated three or four times at intervals of a week in obstinate cases.

Report of the Commission on the Prophylaxis of Tuberculosis (*Gazette Hebdomadaire des Sciences Médicales de Bordeaux*).—The members of this commission were: MM. Terneuil, German Sée, Dujardin-Beaumetz, Cornil, and Villemin; and the most important of their conclusions are:—

That the terrible mortality due to tuberculosis must not be reckoned only from the cases of phthisis, but that a large number of examples of bronchitis, pleurisy, meningitis, peritonitis, enteritis, diseases of bones and their articulations, indolent abscess and others, are due to the same fatal and protean source.

Tuberculosis is an infectious, parasitic malady caused by a microbe, but can only be conveyed to healthy individuals under special circumstances. Besides its transmission by descent (*a point which is, at least, doubtful.—Trans.*), the microbes can gain entrance aërially by the organs of respiration, by the stomach mixed with food, by the mucous membranes, and by the skin through wounds, scratches, or punctures.

The most common and active source of contagion is to be found in the sputum of consumptives. In its liquid state this has little activity, and can only very rarely do mischief; it is when dried and reduced to powder by attrition that it is most dangerous. When expectorated on the ground, the floor, or the surface of walls, on one's clothes, carpets, bed coverings and curtains, even in handkerchiefs or napkins, it may readily be reduced to this pulverent form, and then be distributed by the air, to be absorbed by the lungs, settle on one's skin, on mucous surfaces, or become mixed with food. In the fæces, also, of the phthisical, the microbe exists, and may be disseminated by similar means. Therefore the utmost care should be taken in the reception and disposal of the sputa; the spittoon should always contain water or some antiseptic liquid—never sand, sawdust or ashes. The contents should be thrown daily into the fire, and the vessel well washed with boiling water. It should never be emptied into drains, on dunghills, or on the soil of gardens.

Handkerchiefs should never be allowed to become dry before washing, but be put into water as soon as possible after use. But the best plan is to use some cheap material and burn it. (The Chinese custom of paper *mouchoirs* might well be adopted in these cases.—*Trans.*)

A healthy person should not sleep in the same bed as a consumptive, nor, if it can be avoided, in the same room.

In hotels and establishments devoted to the use of consumptives, the furniture should be of the simplest kind and readily washed; and all textile fabrics should be disinfected before a change of occupancy by heating in steam under pressure.

Besides the chances of human contamination, there is the ever-present danger of infection by tuberculous animals. The fatal microbe may be found in the milk, the flesh, and the blood of those used for the food of man; in beef, in cows', goats', and asses' milk, the flesh of rabbits and fowls.

Cow's milk is most frequently infected, that of the goat and ass much more rarely. But it is safer to boil them all before used as infants' food. The carcases of all animals slaughtered for food should be jealously examined before the meat is permitted to be sold. There is a horrible practice, common in France, of people frequenting the *abattoirs* for the sake of drinking the warm blood—one is glad to hear that it is exceedingly dangerous; and meat should not be cooked in large joints, since the bacillus can stand a high temperature with impunity. The children of tubercular parents are most inimical to the disease, and this is obviously true, apart from the possibility of congenital infection.

Apepsia, Dyspepsia and Bradypepsia. Dr. Torras y Pascual (*Revista de Ciencias Médicas*).—All pathologists, writers, and observers are in accord in wishing to banish the word dyspepsia from our nosology, but it is one we are constantly using and hearing used without protest and yet without any warrant for its employment. It is like the equally convenient and equally inexact phrase "congestion of the lungs" which we carelessly apply to conditions as diverse and as little explained by it. And why is this? It would seem to be due to our

fondness for prescribing and administering the innumerable so-called remedies of the druggist, in place of carefully working out a rational system of therapeutics for ourselves. It is much easier to direct the taking of a little bi-carbonate of soda, of bismuth, of calumba and ginger, than to endeavour to discover amongst the complex chemical and mechanical problems of digestion and assimilation, which organ, which function or which ferment is in fault. "To know what we do, and why we do it, is a rare faculty," says Bouchard, "but to the doctor it is entirely novel." ("*El saber lo que se hace y el porqué se hace, es cosa rara; para el médico es cosa nueva.*)"

Such a prescription as the above is given to relieve pain; then we give diastase, pepsine, pancreatine, papaine, myrosine and so on to relieve the stomach of its work and duties altogether. Or the stomach is washed out with a syphon, paralysed hydraulically and allowed to set to work once more. This is pure empiricism; treating the results of a disease instead of the disease itself, or a disease in place of a patient who is suffering from it.

Ever since the time of Galen, and probably long before, bradypepsia and apepsia—the former (from *βραδυς, slow*) simply meaning an unusual prolongation of the digestive act, the latter its arrest altogether. The term dyspepsia was invented by y de Goris much later, and applied to a condition characterized by sour eructations, fœtid dejections and evidence of putrefactive decomposition of the food. It meant, then, a state not merely mechanical, nor simply unduly prolonged, nor of complete inactivity, but a chemical change which leads to decay in place of disintegration. If the word were used strictly in this sense it would be unobjectionable and would have a clear and precise meaning, but this is exactly what is rarely done.

Accepting this definition one understands why the word occurs so rarely in the lists of cases treated by specialists. In fact, the cases of chemically defective digestion due to some known cause such as cancer, chronic gastritis, mucous catarrh, ulcer, and so on, are rare compared with those of gastro-enteric atony, paresis of the muscular fibres of the stomach and intestines, which constitute the bradypepsia so often confounded with it.

If one is unaware of this condition, or disregards it, it results that what was at first simply an indolent digestion, becomes a painful one; there is gaseous distention, the partially digested food lies a long time in the colon, irritating the mucous lining, and gives rise to colic and the severe pain of flatulent distention. This pain is really confined to the transverse colon, but is referred by the patient to the stomach, and very often to the heart; and then, as the pain is often treated as if it were the source of the evil, a very simple case is mismanaged into one of chronic discomfort. Soda and opium are given, when nux vomica and aloes would have rectified the whole mischief.

Ricord.—"Le dix-huitième siècle avait une dernière sottise à commettre avant d'expirer"—dit un jour Ricord—"celle de me mettre au monde. Je suis né le 31 décembre, 1799, à onze heures trois quarts du soir."—(*Le Progrès Médical*).

Utilite du pavage en bois.—Le pavage en bois, ça permit aux habitants de dormir? Je crois bien . . . . le nombre de naissances a diminué dans toutes les rues pavées en cette mamière.—(*Journal d'Accouchements*).

[Erratum.—Insert "of Fowler's Solution" after "half an ounce," p. 704, line 38, November issue of P.M.J.]

III.—NOTES FROM FRENCH JOURNALS.

By H. R. Hatherly, M.R.C.S.

Influence of Anæsthetics on the Force of Respiratory Movements (*Le Progrès Medical*).—Dr. Langlois, of Paris, has observed that anæsthetics diminish the force of respiratory movements. Dr. Richet noticed, with him, that the expiration of a dog under the influence of morphia or of chloral was rapidly affected, whilst the inspiratory force was scarcely influenced. The reason is that inspiration is normally automatic, whilst expiration is due above all to elasticity. In administering an anæsthetic, it is the expiratory movement which should be most carefully watched.

Action of the Liver on Poisons (*Le Progrès Medical*).—Dr. Roger, of Paris, points out that the liver modifies the toxic effects of several poisons, as has already been noted by Schiff, Hegar, Jacques, and Lautenbach. He has performed certain experiments which demonstrate clearly its modifying action with regard to—nicotine, atropine, quinine, and strychnine; also certain putrid and intestinal poisons, peptones, and some salts, particularly ammoniacal salts. On the other hand, the liver exercises no influence over other substances, such as digitaline, some salts (potash and soda), glycerine, etc. The liver, therefore, like the kidney, possesses an elective action. To control these results it is necessary that the poison should be absorbed very slowly. In the case of a diseased liver (cirrhosis, fatty degeneration, etc.), in which the parenchyma no longer contains glycogen, the liver does not act on poisons, but it suffices to administer substance capable of forming glycogen to see the hepatic gland again competent to transform poisons. The action of the healthy liver is continually exerted against toxic substances in the system, it is still more marked in those infectious diseases in which decided toxic effects are produced. Some clinical facts go to prove that many morbid symptoms are due to insufficiency of the liver in regard to poisons.

Pathogenesis of the Microbes contained in Malignant Tumours (*Le Progrès Medical*).—Dr. Verneuil has directed attention to the fact that the tissues, which are the seat of malignant neoplasms (cancers, sarcomas, epitheliomas, etc.), may, at a given moment, be invaded by divers microbes, the origin, species, and nature of which, it has, so far, been impossible to determine. This invasion, the causes and mechanism of which are alike unknown, may remain latent for an indefinite period, but in certain cases, in the evolution and nutrition of the tumour, it may lead to several modifications, such as the rapid enlargement, the softening, or the ulceration of the part affected. Microbes are not to be found in all neoplasms, or even in all neoplasms of the same kind, nor yet in every portion of the neoplasm invaded. They are not to be found, for instance, in lipomas or in pure fibromas; they cannot be found in the early stages of sarcoma or cancer, in which the progress is slow, and the growth is covered by healthy skin; on the other hand they are nearly always to be found in softened and ulcerated tumours. These microbes, besides their irritant, phlogogenic, and pyrogenic action, which they exercise locally even on the diseased tissue possess other pathogenic properties, which may affect the whole system. Thus, so far as an opinion can be found, they may give rise to a more or less intense and irregular febrile condition, whilst they are pent up in a tumour about to grow rapidly or to soften. Moreover, during the removal of a tumour, they may impregnate the fluids contained in the softened parts, infect the operative wound, and so inoculate it as to develope speticæmia, which may lead even to death. The knowledge of this last fact pleads strongly in favour of the removal of malignant neoplasms, so desirable from every point of view, and suggests forcibly to surgeons the necessity of adopting preventive measures, both during and after operations, for the extirpation of tumours infected with microbes.

Bovine Pleuro-Pneumonia (*Le Progrès Medical*).—M. Arloing, who has been studying the lesions due to contagious pleuro-pneumonia in cattle, has succeeded in isolating four distinct species of microbe from the diseased lung. It is probable, however, that one species alone constitutes the essential virus.

Poisoning by Creoline (*Le Progrès Medical*).—Dr. Von Ackeren records a case which he is pleased to describe as one of poisoning by creoline. A person wishing to commit suicide swallowed eight ounces of creoline; after a few days illness he completely recovered. Creoline can hardly be reckoned amongst the more deadly poisons.

New Treatment of Extensive Prolapse of Rectum (*Le Progrès Medical*).—Dr. Schwartz, of Paris, has recently operated on a patient suffering from extensive prolapse of rectum, complicated by epilepsy. The anterior portion of the prolapse involved the small intestine constituting a true hernia. It was impracticable to use any cutting instrument on account of the peritoneal *cul de sac* situated in front, and the difficulties of antiseptic treatment. There was no contractility of the anal sphincter; the whole of the hand could be introduced. He resolved to operate on the intestine without resection, and to contract it so as to form a new sphincter. His first idea was to denude the intestine of strips of mucous membrane lineally, and stitch the edges together, but he was obliged to abandon this idea on account of the hæmorrhage. He then substituted six broad lines produced by a thermo-cautery. He then dissected away the surface of the anterior portion of the perineum (which permitted the prolapse) four centimetrés in width, and two in height. The whole was sutured with four strong silver wires. The rectum was tamponned, and the whole dusted with iodoform. A period of excitement followed, rendering a straight jacket necessary. Healing progressed favourably, although one of the sutures gave way; a fistula was formed, but subsequently healed. Nine months after the operation the perineum was entirely restored, and the sphincter was active. There is no prolapse of the rectum. The epileptic condition is modified, there having been only one attack since the operation. A similar operation was performed by Dr. Duret previously on another patient. (Dr. Schwartz omits to state the sex of the patient.)

Cholecystectomy for Biliary Fistula (*Le Progrès Medical*).—Dr. Michaux, of Paris, has recently had a successful case. The operation consisted in dissecting down to the gall-bladder, which was found to contain two gall-stones; then having previously ascertained

that the ductus choledochus was patent, two ligatures were applied, and the fistula was divided between them. The patient made a good recovery.

Lipoma of the Breast (*Le Progrès Medical*).—Lipoma of the breast is a rare disease, even in the female, only three cases being recorded. Dr. Quierel, of Marseilles, has recently met with a case in a man, æt. sixty-four. The lipoma was as large as a child's head.

Progress of Cholera in Mesopotamia (*Le Progrès Medical*).—According to Dr. Proust the actual increase of cholera in Mesopotamia demands from Russia the strictest sanitary precautions in the neighbourhood of the town of Recht, at the south of the Caspian sea. This town is only two hours walking distance from the port of Enselli, which is in daily communication with Bokhara and Afghanistan. Cholera has already appeared at Kerinanshah and Hamadan. It is, therefore, a necessity that Russia should protect Europe on the Persian frontier, or we may have to fear an epidemic similar to those of 1830 and 1846.

Abdominal Hysterectomy, followed by Insanity.—Dr. Polaillon, surgeon to the Hospital of La Pitié, reports in *L'Union Médicale*, a successful case of abdominal hysterectomy; the patient recovered from the operation, but during convalescence became insane.

Corrosive Sublimate in Gangrene of the Lungs (*L'Union Médicale*).—Dr. Korany has found that inhalations of twenty cubic centimetérs of a solution of corrosive sublimate (5 centigrammes to a 1000 grammes of water), repeated three times daily, have been successful.

Extirpation of the Larynx (*L'Union Médicale*).—Professor Demous, of Bordeaux, has exhibited a patient in whom he had removed two and a years previously the whole of the larynx for a circumscribed epithelioma of the right vocal cord. The patient did not wear any phonetic apparatus, but was able by certain movements of the tongue and lips to speak intelligibly, although in a low tone.

Removal of Tumours (*L'Union Médicale*).—Dr. Roux, of Lausanne has removed an immense chondro-sarcoma of the iliac bone; he disarticulated the whole bone after separating it from all its muscular attachments. The bone was partially reproduced, and two years after the operation the patient was in good health and able to pursue his usual business. Dr. Thiriar, of Brussels, has removed a fibro-lipoma of the cellular capsule of the kidney, weighing eleven kilogrammes. It was at first mistaken for an ovarian cyst, and laparotomy was followed by nephrectomy. Recovery was rapid. Dr. Boutaresco, of Buccharest, has removed a double cystic goitre, which was threatening suffocation behind the sternum. Each half was removed separately at an interval of seven months. The patient was cured although the retro sternal portion was left.

Formation of Urinary Meatus from the Ureter in the Side (*L'Union Médicale*).—Dr. Le Dentu has performed this operation for a patient who was threatened with death from retention of urine caused by a tumour. Urine was voided freely through the artificial urinary passage, but the patient died of cachexia the fourteenth day after the operation.

Butylchloral for Neuralgia of the Trifacial (*Journal de Medicine*).—According to Leibreich, butylchloral possesses in addition to its soporific properties, a truly specific action on the trifacial nerve, anæsthesia is produced along the whole of its course after the administration of from one to three grammes of this drug.

Sterilised Milk for the Alimentation of Children (*Union Pharmaceutique*).—Sterilised milk is an excellent food for young children, and it is hoped that its introduction may diminish the great mortality attached to this period of life. The municipality of Liepzig has sent a circular to all the chemists in the town to ask if they would undertake to provide sterilised milk after the method of Soxhlet, a process requiring some skill. The sale of this milk will be a new branch of business for chemists.

Treatment of Thrush by Saccharin (*Journal de Medicine de Paris*).—Ten consecutive cases of thrush following measles have been treated by Dr. Fourrier by mopping with a solution of saccharin in alcohol (1 in 50). In eight cases the deposit disappeared in from twenty-four to thirty-six hours. In the other two cases three days were required. Dr. Fourrier orders the mouth to be mopped out five times daily.

Illegal Practice (*Journal de Mèdicine*).—A widow, named Aglaé Bathaupieu Barouge, has recently been prosecuted for roguery and illegal practice of medicine. One of the witnesses testified that she had consulted Widow Barouge about her daughter, who, she alleged, was unable to say no to anyone, and whose figure beneath her apron was assuming such proportions as to cause grave anxiety in the family circle. Madame Barouge made the sign of the cross on the back and stomach, and then assured the witness that the demon in her daughter's inside had flown away. The prescription given her by the prisoner was as follows: "Take three tails of red herrings, and soak them in holy water, add two carrots, a pinch of hair from a white cat, which has been cut six months, three teaspoonfuls of water from Lourdes, etc., the whole to be boiled for six hours and thirty-seven minutes, repeating the meanwhile every quarter of an hour five *paters* and five *aves*. The mixture to be filtered through pure linen. Twenty-nine drops to be poured on the navel every night whilst saying three times, 'Gentle Jesus, Mèlie has it no longer.'" Other witnesses were called who gave similiar testimony. One old maid deposed that she had been defrauded of 400 francs to get rid of a moustache which still remained; and the son of a policeman who indulged in a fond hope that hair would grow on his chin, also found that the remedies prescribed were a snare and a delusion. Widow Barouge, a little wizened old woman, with a hook nose, and who was gorgeously arrayed in a black silk dress trimmed with lace, and who was loaded with jewels, appeared to attach little importance to the proceedings, inasmuch as the coffee grounds she had examined in the morning foretold she would be acquitted. She was sentenced to three months imprisonment for roguery, and an additional fortnight's imprisonment with a fine of 200 francs for illegal practice of medicine, notwithstanding the coffee grounds.

Hydrophobia (*Gazette Hebdomadaire des Sciences Médicales de Bordeaux*).—A man named Rascol, a rural postman, was bitten by a dog on the 28th February, 1889, through two thicknesses of trousers, and was sent to the Pasteur Institute, by his administration to undergo treatment. He was treated for fourteen days, but, nevertheless, died of hydrophobic paralysis on the 14th of April last, forty-six days after being bitten. A neighbour of his who was bitten just before Rascol, on the same day and by the same dog, continues in good health seven months after his bites. He has undergone no treatment.

IV.—NOTES FROM RUSSIAN, POLISH, AND SWISS JOURNALS.

By Valerius Idelson, M.D., Berne.

On the Influence of General Anæsthetics on the Respiration.—At the first International Congress of Physiology at Basle, Dr. P. Langlois, of Paris, read a paper on this subject (*Correspondenz-Blatt fuer Schweizer Aerzte*, October 15th, 1889, p. 612), based on some experiments carried out by himself, conjointly with Professor Richet. The essential outcome of the researches is this: Under the influence of all general anæsthetics, more especially under that of hydrate of chloral, the expiratory movements become invariably affected (weakened) to a far more considerable degree than the inspiratory ones. Given an animal in the state of a deep narcosis, an artificial resistance set to the expiratory movements of the chest rapidly gives rise to asphyxia, and that even when the said resistance amounts only to some ten or twenty millimetres Hg. A much higher pressure is required to induce an inspiratory asphyxia. The fact certainly deserves attention of all who happen to practise general anæsthesia in man or animals for therapeutic or physiological purposes.

On Surgical Treatment of Empyema.—Following the suggestion by Professor Courvoisier, Dr. Benedict Simonett, of Basle (*Basle Inaugural Dissertation*, 1889, pp. 47), has undertaken a comparative statistical inquiry into the results obtained in empyema from surgical treatment after various methods in vogue. His materials consisted of (*a*) fifteen cases operated upon by Professor Courvoisier (in the Riehen Diaconissen-Spital). In the fifteen patients the following sixteen operations were performed: One simple tapping (which failed to bring any relief, hence a subsequent resection of rib became necessary); thirteen simple resections of rib (nine with good results, two patients soon died from phthisis and miliary tuberculosis respectively, in one a permanent fistula remained, and in one two thoracoplastic operations became subsequently necessary); and two thoracoplastics (in the case just mentioned). In the nine cases cured by resection of rib, healing took place on an average in thirty-nine days. (*b*) Five cases treated by Professor Immermann (in the Basle Buergerspital) after Buelau's method with aspiration and drainage. Of the five, two referred to simple empyema, and were cured in 153 and 73 days respectively; in the other three, pyo-pneumothorax existed; two of them died, the third (a phthisic patient) being still under observation. (*c*) Cases collected by the author from international literature. As may be gathered from the author's three tables (which include the twenty cases mentioned above), in 107 cases simple thoracotomy (by an intercostal incision) was performed, with sixty cures, thirty-five deaths, and twelve failures (permanent

fistule), healing ensuing on an average in seventy-five days. In other seventy-nine cases, simple resection of rib was made, with fifty-five cures, eighteen deaths, and six failures, healing taking place on an average in sixty-three days. In a third group, consisting of fifty two cases, thoracoplastics were resorted to, with twelve cures, thirteen deaths, twenty-four "improvements," and three failures.

The principal general conclusions drawn by Dr. Simonett from his important researches may be summed up as follows: (1) A simple tapping alone is utterly powerless to cure empyema. (2) An intercostal incision alone (without resection of rib) should not be practised even in recent cases, since it favours stagnation of pus, and is apt to unduly protract the course of recovery. (3) The best method is resection of rib, which gives most successful results, and secures a most rapid recovery. Hence, it should be resorted to in all cases of empyema.

On the Action of Naphthaline on the Eye and General System.—In order to study the effects of naphthaline on the eye, Dr. Jozef Kolinski, of Warsaw, has carried out (*Gazeta Lekarska*, 1889, No. 30, p. 603) a long series of very careful and interesting experiments on rabbits, dogs, guinea-pigs, and white mice. The drug was introduced into the animal's system in various doses, shapes, and ways, the individual observations lasting from a score of hours to seven months, and the whole inquiry about eighteen months. The author arrived at the following conclusions:

1. When used in large (toxic) doses, naphthaline gives rise to a peculiar train of changes in the eye, as well as in almost all internal organs of the body.

2. On the whole, the drug appears to create in the system a pronounced tendency to hæmorrhage—something like a "hæmorrhagic diathesis."

3. The morbid changes anywhere in the body begin with hæmorrhages into tissues.

4. The primary ocular changes consist in extravasations of the blood into the choroid coat (between the retina and pigment layer), which swiftly lead to circumscribed separation of the retina and vitreous body.

5. In connection with the lesions in the choroid, retina, and vitreous body, there develops, in a secondary way, a genuine cataract of a peculiar type.

6. Speaking generally, the naphthaline cataract arises in the same manner as an ordinary soft cataract, coming nearest to a diabetic one.

7. In cases of acute naphthaline poisoning (induced by large doses of the drug), the development of the cataract proceeds very rapidly, the process reaching its height sometimes in a few hours. It is always accompanied by an intense swelling of the lens, which speedily assumes an almost regular spheroid shape. Fairly often, a considerable tumefaction of the posterior wall of the capsule is also observed.

8. In initial stages of the cataract there arises an irregular astigmatism, which is to be explained partly by some accumulation of Morgagni's aqueous fluid beneath the capsule, and partly by a circumscribed degeneration of the under-capsular cortical mass.

9. In the retina, vitreous bony, and cornea (and sometimes in all bon-vascular ocular structures) there are discovered peculiar crystallinic nodies, which prove to consist of phosphates of calcium.

10. The concretions are met with only in cases of chronic naphthaline poisoning.

11. In course of time, the cataract undergoes a partial absorption. [The author never yet saw a complete resolution of the process.]

12. The changes in the vitreous body seem to be of a permanent nature; at least, they remain *in statu quo* even after the lapse of many months.

13. The lesions in the retina and choroid show with time some improvement. A complete restoration of a healthy condition of the coats is, on obvious grounds, impossible.

On the Influence of Saccharin on the Assimilation and Metabolism of Nitrogen in Healthy Persons.—In a preliminary note in the *Vratch*, No. 38, 1889, p. 836, Dr. Semïon L. Savitzky, of St. Petersburg, describes a course of experiments, carried out by him in Professor V. A. Manassein's clinic, in order to elucidate the action of Fahlberg's saccharin on the assimilation and metamorphosis of proteids in healthy subjects. In all, five observations (each of ten days' duration) were made. The substance was given internally, in the daily dose varying between 0.2 and 0.4 gramme. The essential outcome of the researches may be given somewhat as follows:

1. Saccharin does not in the least disturb any digestive processes, the consumers invariably tolerating it perfectly well.

2. In the doses stated, the substance invariably augments the assimilation of nitrogen. [In one of the subjects, the assimilation rose from 86.94 per cent. to 92.74; in a second, from 96.04 to 96.59; in a third, from 91.27 to 93.59; in a fourth, from 92.34 to 93.27; and in the fifth, from 91.21 to 95.83.]

3. But the nitrogenous metabolism always sinks. [In the first patient it decreased from 102.19 per cent. to 86.76; in the second, from 117.91 to 101.58; in the third, from 87.27 to 82.71; in the fourth from 86.75 to 76.03; and in the fifth, from 99.94 to 86.42.]

4. In the latter regard, saccharin closely resembles quinine, which similarly inhibits the proteid metamorphosis. In either case, the phenomenon should be attributed, probably, to anti-fermentative and antiseptic properties of the substances.

5. The question of the admissibility of saccharin as an article of human diet remains yet open. It can be settled only on the ground of further careful and prolonged experiments, elucidating the influence produced by the ingestion of the substance on the assimilation and metamorphosis of non-nitrogenous constituents of human food. At all events, an ultimate conclusion requires a considerable caution, since a continuous or habitual depression of the nitrogenous metabolism cannot possibly remain without certain marked consequences for the consumer's organism.

On the Effects of General Hot Sand Baths.—In the Russian popular medicine, hot sand baths have been from time immemorial enjoying a high reputation as a remedial means for various cachectic diseases. Scientific medicine, however, ignores the popular remedy almost completely even now-a-days, when any other baths (similarly borrowed of popular medicine) attract so much attention and study. In fact, the list of contributions to our scientific knowledge of sand baths remains yet exceedingly short, the only contributors being Flemming, Suchard, Evsëënko (*vide* the *London Medical Record*, January, 1884, p. 11), Bertenson and Voronikhin, and Bëlakovsky. In view of the paucity of the literature of the subject, Dr. Nikolai V. Parïinsky, of Evpatoria (*Vratch*, No. 37, 1889, p. 809), has quite recently undertaken researches experimental concerning the physiological and therapeutic action of general natural hot sand baths. The experiments (referring to twenty-five soldiers suffering from various rheumatic affections) were conducted on the sloping coast of the Black Sea, in sunny and still summer days. On each occasion, about 10 a.m., dry sand was heaped up in the shape of small-sized mounds, just sufficient to each admit a human body. As a rule, in an hour or so the upper layers of such sand heaps became warmed up to from 42° to 44° Reaum., and the deeper ones up to from 32° to 38°. The sand was then thoroughly blended, to give a medium having the temperature of 38° R., after which the patient (stripped to the skin, of course) was laid down, and covered from his feet up to his neck with an even sand layer, about ten or fifteen centimetres thick. The bath usually lasted about half an hour, and was followed by a tepid water bath (just to wash out the body). The principal corollaries drawn by Dr. Parïinsky from his interesting observations (103 in number) may be summarised thus:

1. Under the influence of a sand bath at 38° R., the patient's axillary temperature invariably rises. The elevation oscillates between 0.1° and and 1.3° C., amounting on an average to 0.53°.

2. About the bath's termination, the pulse usually (in 94.3 per cent. of cases) becomes quicker. The acceleration varies from four to twenty beats per minute, the average being 8.6.

3. The respiration, as a rule (in 86.7 per cent.), also somewhat quickens, the average surplus being 3.4 per minute, the maximal 8.

4. The sand bath gives rise to an intense perspiration, which commences in about five minutes after the patient has been covered with sand. In twenty minutes his body is found to be plastered all over with a wet sand layer as thick as a finger's breadth. The total loss in the body's weight after a bath oscillates between a quarter and four and a quarter (Russian) pounds, amounting on an average to 1.84 (753 grammes).

5. The blood-pressure after a bath rises two or three divisions of Basch's sphygmometer.

6. The cutaneous sensibility (tested by Burg's æsthesiometer) commonly (in 54.6 per cent. of cases) remains unaltered, but fairly frequently (in 38.6 per cent.) increases, while now and then (in 6.8) it decreases.

7. Speaking generally, a sand bath acts like a hot bath of any other kind, differing only from it in quantative regards.

8. Sand baths are tolerated very well, and are liked very much, even by patients suffering from cardiac or vascular disease.

9. In certain cases their use is followed by a very rapid and considerable amelioration of the patient's state.

10. On the whole, they most decidedly deserve an extensive employment for therapeutic purposes.

Ammonia as an Antidote in Cocaine Poisoning.—Dr. Agafon J. Golovkoff, of Tiflis, relates (*Proceedings of the Caucasian Medical Society*, 1889, Sept. 13th, p. 206) the following interesting case of poisoning by cocaine, which, apparently, points out that ammonia affords a good antidote for the alkaloid. A delicate and nervous lady, suffering from agonising toothache (caused by caries of a wisdom tooth), was

treated by the hypodermic injection of a 2 per cent. solution of hydrochlorate of cocaine, a (Pravaz) syringeful at a time. The first injection was tolerated, seemingly quite well, but a second (four and a half hours after the former) was followed in five minutes by the appearance of general restlessness and excitement, dilatation of pupils, pallor of the integuments, intermittent and accelerated pulse (120 per minute), dyspnœa, and rigors. In another five minutes the frequency of the pulse rose to 200 per minute, and that of the respiration to 60, while the cardiac sounds assumed a "metallic character," and became audible at the distance of two paces from the patient. There appeared intense cardiac pain, backache (especially severe about the loins), fear of impending death, and convulsion of all the four extremities. Amyl nitrite was at first tried (in the shape of inhalations, two drops from a handkerchief), but was at once discontinued, since it still further increased dyspnœa, cardiac pain, and frequency of the pulse. Liquor ammoniæ causticæ happening to be at hand, the author commenced to administer it both internally—four or five drops every five or ten minutes—and in the shape of inhalations. In half an hour all urgent symptoms subsided. By the end of two and a half hours there remained only general weakness and lassitude with some epigastric pain [the latter probably from a liberal use of ammonia?—*Reporter*] which disappeared in about two days. The toothache continued unabated for a fortnight.

[Ammonia internally, together with ether, brandy, black coffee, and other means, was also successfully employed in a case of cocaine poisoning, reported by Dr. Gooding in the *Lancet*, February 15th, 1888, p. 394.—*Reporter.*]

Sea-Sand Baths in Rachitis and Rheumatism.—According to Dr. Vasily G. Sürovtzeff, of Ekaterinodar (*Proceedings of the Arkhangelsk Medical Society*, 1889, vol. i., p. 39), the peasantry and generally "common people" inhabiting the coasts of the White Sea use to treat rachitis by means of hot sea-sand baths, which are arranged in two ways: either the sand is previously dried and duly warmed in a Russian stove (somewhat resembling a baker's oven), after which the child is covered all over with the substance; or the sand is admixed to an ordinary hot-water bath. The same treatment is resorted to by adults in cases of chronic rheumatism. In summer time the patient of the kind is said to go to the sea coast, where he buries himself in sand pleasantly heated by sun-rays, then rubs his body with it, and in conclusion, takes a bath in the sea to wash off the sand plaster.

V.—PUBLIC HEALTH.

We published in our October issue a full account of the value of Pasteur's method from the pen of Dr. Maguire. We now present two papers on the other side, one contributed to the *Medical Record*, New York, the other by Dr. Lancereaux.

Anti-Rabic Inoculations an Unscientific Method in the Prevention of Hydrophobia. By Joseph Drzewiecki, M.D. (Ordinary Physician in the University Clinic of the Holy Ghost Hospital, Warsaw, Poland).—The question as to the efficiency of Pasteur's method of prevention of hydrophobia has been subjected to considerable criticism, and from time to time voices of scientific men have been heard in opposition, the greatest objections coming from Frisch, Ullman, and Peter. Although Pasteur replied to Frisch's objections, yet his answer was very feeble and unsatisfactory. From Pasteur's whole defence, the most characteristic argument is addressed to Professor Peter, *i.e.*, that he cannot dispute with incompetent persons, as Peter had never made experiments. The *France Médicale*, July 7th, 1888, noticing this fact, remarked that with similar arguments it was difficult to convince anybody, and that now we live in a strange time when the chemist—experimentator, and not the physician—categorically accuses the professor and clinicist as incompetent in justifying the therapeutic methods. The only argument which Pasteur always states in favour of his method is the statistics of inoculations. However, as we shall show further on, it cannot be considered as scientific, and therefore it cannot be seriously treated. The editor of the *Journal de Médecine de Paris* showed upon what a weak basis Pasteur supported his statistics, and if they were seriously treated we should receive a greater percentage of mortality.

The English Commission had personally inquired into 90 cases treated by M. Pasteur, but only 24 of these were said to have been bitten by undoubtedly rabid dogs, so that the 8 fatal in this number were far in excess of the usual proportion of fatalities in cases of bites of rabid dogs—viz., 5 per cent. The report had reckoned that of the 2,682 cases treated at the Pasteur Institute, the mortality should have been 130 instead of 40; but it ought to have been stated that only 233 of the cases were found to have been bitten by rabid animals, which would have given a mortality of only 15 if untreated. M. Lutaud contended that the Pasteurian method had increased the mortality instead of diminishing it. Before its adoption the annual average mortality in France was 30. The actual mortality in France during 1886 was 42, of which 25 had been treated by Pasteur.[1]

As Pasteur defends his method by statistics, let us cite other statistics. Dr. Kishensky[2] states cases, selected from the archives of the Katharine Hospital in Moscow. The whole number of cases amounted to 693, and from this number, excluding cases bitten by other animals, 591 were bitten by mad dogs, and there died only 8, or 1.35 per cent. But the author asserts that in this manner statistics cannot be treated, because about many of the cases it was not known whether they had been bitten by rabid dogs, and therefore omits all such cases, and gives only those about which there was no doubt of their having been bitten by unquestionably rabid dogs. Some of them remain in the hospital under medical observation during at least six weeks, but the greater part of them three months and longer.

According to these statistics it is shown that out of 307 persons bitten by unquestionably rabid dogs, 18 were bitten in the head, 90 in the hands, 25 in the feet, 170 in places covered with clothes, and 4 in places not indicated. Of 18 bitten in the head 4 died, or 22.2 per cent.; of 90 bitten in the hands, 2 died, or 2.2 per cent.; of 25 bitten in the feet, no death, and of 170 bitten through the clothes, 1 only died, or 0.59 per cent. If we add to the deaths another, belonging to the 4 about whom it is not known where they were bitten, we have 8 deaths, or 2.6 per cent.

Out of 24 cases severely bitten by rabid wolves, 2 arrived at the hospital with the symptoms of hydrophobia; 5 were in the hospital only during six weeks, 4 of them were discharged in good health, and 1, very severely bitten, died of septicæmia. The remaining 17 cases were under observation during eight weeks. Of this number 11 were bitten in the head, 3 in the hands, and 3 in places not indicated; 5 of them died, showing a mortality of 30 per cent., but, according to Pasteur, it is 82 per cent. All those who died had extensive wounds on the head. The author concludes that a greater number of persons died from the bite of wolves than from that of dogs, because the wounds of the former are larger and more numerous. Of 18 cases bitten by rabid cats only 3 died. Of 17 cases bitten by rabid horses, 9 were in the hospital during three months, and none of them of hydrophobia, but 1 died of erysipelas and another of septicæmia. Of 4 bitten by a rabid dog, none fell ill. To this number we must add 4 cases bitten by rabid men, 1 by a white bear, and 1 by a rabid squirrel. Thus the whole number bitten by rabid animals—396—there died 18, or 4.52 per cent.

If we now consider that in Pasteur's statistics are included many cases unproved,[3] and if to this we add the cases given by Professor Peter, of which one died, as Peter asserts, in consequence of the antirabic intensive inoculations, and another died from rabies two years and three months after the antirabic treatment, we arrive at the conviction that the Pasteurian method has no value. In order to accept the method of preventive inoculations as valuable, it is necessary to prove that it prevents the development of hydrophobia in men. Pasteur only proved that his method prevents the development of rabies in dogs. Still, the experiments made in this direction by Dr. Frisch do not demonstrate the value of the inoculations, and Pasteur explains the unsuccessful results of Frisch by the fact that the latter transferred the experiments from dogs to rabbits. But if it is erroneous to transfer the experiments from dogs to rabbits, it is still more so to transfer them to men, as Pasteur does. Until now he has not yet proved that the inoculations prevent hydrophobia in men. The whole series of fatal cases treated in his Institute prove just the contrary.

1. On April 1st of last year a soldier of the name of Marinot, inoculated at the Pasteur Institute, died from rabies at Val-de-Grace.

2. On May 16th, a yonng man (Poulet), æt. twenty, died at the Hôtel Dieu Hospital from rabies. He had been bitten by a mad dog on December 6, 1887, and was treated at the Pasteut Institute from December 8, 1887, to January 6, 1888.[4]

3. O—— died from rabies, bitten on April 23rd, and inoculated from April 26th to May 12th last year.[5]

4. On August 8th, a young man named Guers, æt. twenty-two, died at the Neckar Hospital at Paris from convulsive rabies. He had

[2] *Vratch*, Nos. 44 and 45, 1887.

[3] *France Médicale* and *Union Médicale* (January 6, 1887) published a letter of Dr. Ziegel, in which he writes that ten soldiers bitten by a dog, suspected to be mad, were sent for treatment to Pasteur. After their return to Wilna, they found the dog that had bitten them in a perfect state of health, and five months afterward the soldiers and the dog were quite well.

[4] *Semaine Médicale*, July 4, 1888.

[5] *Ibid.*, July 25, 1888.

been bitten by a mad dog on July 13th, and was treated at the Pasteur Institute from the 16th.[6]

5. On June 20th, a child (Bertin), eighteen months old, died from rabies at Gentilly (Seine). The child, who had been bitten on May 15th, was inoculated at the Pasteur Institute on the 17th, and the treatment was continued for twenty-four days. The first symptoms became manifest about the eighth day after the completion of the treatment by antirabic inoculations.[7]

6. On July 23rd, a man, æt. twenty-eight, died of rabies at the Hôtel Dieu of St. Etienne. He had been bitten by a rabid cat on June 16th, aud was treated at the Pasteur Institute from June 20th to July 7th.

7. A child, at Marseilles, thirty-one months old, who was bitten on May 9th by a rabid dog, and treated at the Pasteur Institute from May 14th to June 9th, died from rabies on June 23rd.

8. An inhabitant of Chatenay, æt. forty-four, who was bitten on March 25th by a rabid cat, and treated at the Pasteur Institute from March 26th to April 12th, died from rabies on July 30th.

9. Madame Sarazin, of Saint-Maurice, in Switzerland, æt. forty-four, who was bitten on July 1st by a mad dog, and treated at the Pasteur Institute from the 4th of the same month, died from rabies at the Hôpital Broussais, in Paris, on August 4th.[8]

10. C. W. Dean described a fatal case in a boy, five years of age, bitten by a mad dog, who had been treated at the Pasteur Institute, and discharged as recovered.[9]

11. At a meeting of the Academy of Medicine in Paris, on January 4th, 1888, Professor Peter communicated a case, observed by Dr. Miquel concerning a certain Révaillac, twenty years of age, bitten by a dog considered mad by a veterinary surgeon; the dog was killed the next day. The place of the bite was cauterized, and forty-eight hours after the bite had taken place the patient came to the Pasteur Institute. During twelve days injections were made three times a day in the hypochondrium. On December 12th, 1887, the patient commenced to feel a great pain in the place of the injections and not in the place of the bite. In a short time general debility followed. The next day he was apathetic and dejected, and four days afterward died with foam on his lips. The day before his death he had convulsions and difficulty in swallowing. Death followed six weeks from the day of the bite.

12. In the *Semaine Médicale*,[10] Professor Peter, speaking about microbes and alkaloids, states that Berger died six months, and Sinardot died two years and three months, after injections at the Institute.

Here we have some of the unsuccessful results of the Pasteurian treatment, selected from the literature of last year. Pasteur himself, knowing well the insufficiency of the inoculations, found it advisable to take a certain precaution, namely, that his method cures only such cases where the bite is not deep and not on the head. What is the good of such a precaution? Is it not evident that the inoculations help at that time when the virus has not entered into the blood, and are inefficacious if the virus has been introduced?

I cannot understand why Pasteur's method is unsuccessful in cases where bites by rabid animals are large and deep, especially in the face. If the virus acts through the nerves, the least scratch must allow the contact of the virus with the nerves, in which the skin abounds; at last the circulation permits the virus to come in contact with all tissues. Every new method deserves our attention as long as it shows itself efficacious in serious cases which cannot be cured by other methods. Meanwhile, the Pasteurian method includes only slight and doubtful cases, and excludes the serious; in one word, it cures those cases which probably would recover without any inoculations.

Finally, Pasteur asserts that the inoculations weaken the virus introduced by the bite of a rabid animal, *i.e.*, accustom the organism to the virus, no matter whether the unfortunate persons treated by him have or not very violent symptoms of rabies. If the inoculations harden the organism against the virus, then the symptoms of rabies should be very mild, as it is evident in small-pox. In what way, I ask, does Pasteur see the preventive properties of the inoculations? His method neither prevents rabies, nor does it weaken its symptoms.

If we consider the above, and add to it the cases given by Professor Peter, out of which the first died, probably from intensive inoculations, the second in six months, and the third died from rabies two years and three months after the Pasteurian treatment, we must acknowledge that this method can only be of value for veterinary surgeons, but being transferred to men, it is unscientific, and as such must be condemned in the interest of humanity and science.

[9] *Lancet*, June 16, 1888.
[10] Novmber 21, 1888.

I must still mention that the experiments made by Professor Roch, and M. Schutz, professor of the Veterinary School of Berlin, have shown that the mortality from charbon is sensibly the same in vaccinated and unvaccinated animals, and the practice has been nearly entirely abandoned; and, therefore, this Pasteurian method also, which made a great noise in the world and was accepted with enthusiasm, has been proved to be false.

Case of Hydrophobia occurring in a patient previously Inoculated by M. Pasteur, with observations by M. Lancereaux upon the Failure of the Anti-Rabic Treatment (*Journal de Médecine de Paris*, November 10th, 1889).—M. Lancereaux, under whose care the deceased had been, communicated the case, with his observations thereon, to the Council of Public Hygiene and Health of the Seine. At the conclusion of this communication, the President (M. Pasteur being present) enquired if anyone desired to continue the discussion. M. Pasteur remained silent. It should, however, M. Lancereaux observes, be made known how it is that the case and comments have been excluded from the *Bulletin du Conseil d' Hygiene!* The *Semaine Médicale* has sufficient independence to publish the interesting facts observed by M. Lancereaux in the following case:

On the 14th July, 1889, a boy, æt. thirteen years, died in the Hospital la Pitié, having been bitten in the leg by a dog on the 23rd May. This child was under treatment at the Pasteur Institute from the 25th May to the 10th June, the wound having been washed and cleansed by Dr. Vergrade, with the Van Swieten's solution, within an hour of the accident. At the same time, a youth, æt. seventeen years, residing in the same house, was bitten by the same dog, causing two superficial wounds on the thigh. These were cauterised by M. Vergrade by means of a thermo-cautery, a few minutes after their infliction, and like the preceding case, was submitted to Pasteur's anti-rabic treatment. He continues in a healthy state. Another child, æt. six years, was bitten through his shoe. The wound was washed with a solution of phenic acid, and on the 25th May he was taken to Pasteur's laboratory. He continues well. The following are the comments of M. Laucereaux upon these three cases:

"It is necessary, in the first place, to inquire into the differences in the termination of the three cases, otherwise it would be difficult to explain the facts. The survivors, it may be said, have been cured—the one because the wound was cauterised by hot iron soon after the bite, the other because he was bitten through his shoe. The death of the third is explained by the bite having been deep, and not cauterised. Considering the circumstances of these three patients, the interpretation of the facts is difficult. We must, however, take into account a new element—the treatment instituted by M. Pasteur; but if this treatment has cured two out of the three of those bitten, why did the third die? This is the question which really must be put. In other words, if the treatment cures hydrophobia, why not cure it always? This question will doubtless be answered some day, but it has not yet been replied to. I know that, relying upon statistics, M. Pasteur urges that the mortality from hydrophobia has diminished since the introduction of his method, but the statistics here compared have only a relative value. Are statistics admitted as proof in matters of scientific observation and experiment to which medicine belongs? Certainly not. Statistics, according to the celebrated Claude Bernard, cannot furnish scientific truth, and consequently, cannot yield a scientific method. Chemists do not appeal to statistics when they would prove a fact. The reactionary phenomena upon which they operate in determinate conditions are always identical; if not, they address themselves to discover the reason. It cannot be otherwise in medicine and therapeutics. Can we discover in the circumstances related the reason of the therapeutic success in one case, and its failure in another? We know that the patient who died had not been cauterised on the receipt of the wound, but this cannot be the explanation, since another child, bitten by the same dog and not cauterised, continued in good health. In every case it must be by discovering the cause of failure, and not by statistics, that the prevention method must ultimately be judged.

To sum up—three young subjects had been bitten by the same mad dog—one through the leather of the shoe, the second was immediately cauterised; both were inoculated, and did not become rabid. The third was bitten severely, but not cauterised; was inoculated, but became rabid. The Pasteur inoculations are thus shown to have been useless in these three cases; they had not protected from rabies those who were in the conditions said to be protective, and they have not saved from rabies the only one who had been subjected to the measures adapted thereto. Inefficacious as they were in these instances, might they not have proved 'rabific,' as in the case of the unfortunate letter-carrier, Rascol?" (*Journal de Médecine*, October 13th, 1889).

The Singular Poisoning Cases at Leeds.—On Wednesday afternoon, November 13th, two men were discovered in their cabin, at the Leeds Forge Company, Limited, in what was supposed to be a

state of lethargy, but on medical assistance being procured, they were pronounced quite dead. No marks of violence were found upon them, and there appeared to be nothing in the surrounding circumstances of the case to account for their decease together. Acting under instructions from the Leeds Borough Coroner (Mr. J. C. Malcolm), Mr. Scattergood and Mr. Hargreaves, surgeons, proceeded to the Forge to a *post-mortem* examination of the bodies, which had been laid out in a building known as the band-room. Two other surgeons—Mr. W. H. Brown and Mr. A. K. Scattergood—also attended, the former representing the relatives of the deceased. At the request of the solicitors engaged by the different parties who are interested in the result of the inquiry, the Coroner gave his sanction to the attendance of several other surgeons, and Mr. Jessop represented the Leeds Forge Company; Mr. W. H. Brown, who had attended one of the deceased men as his medical adviser, was present on behalf of the relatives of both the deceased; and Mr. J. S. Loe watched the examination on behalf of the Boiler Makers' Association, of which French and Tennick were members, and in which they were insured. The medical gentlemen first made notes as to the outward appearances of the two bodies, and just as Mr. Arthur Scattergood was about to cut open the chest of one of the bodies, he sank down unconscious. The other surgeons left their work to go to his assistance, and while they were attending to him several of them began to feel peculiar symptoms. Finding they were in danger, they lifted Mr. A. Scattergood and proceeded to carry him from the room. At the door Mr. Loe fell down in an unconscious condition. Mr. Spray was also seriously affected, and Mr. T. Scattergood felt a strange twitching about his breast and a swimming sensation in his head, as if he were about to faint. Mr. Arthur Scattergood was carried into an office adjoining the band-room, and there he partially recovered consciousness, but had a second attack, apparently of convulsions. The ambulance was then telephoned for, and he was removed to the house of his father in Park-square, but it was not till about half-past one o'clock that he could be considered out of danger. As all the medical gentlemen felt too ill to proceed with the *post-mortem* examination, and as there appeared to be danger in doing so, Mr. T. Scattergood sealed up the band-room, and communicated with the Coroner. It was suggested that a tent should be erected in the yard, in which the adjourned examination might be made, and the representatives of the Forge Company readily undertook to carry out that arrangement.

After hearing the report from Mr. Scattergood as to the jeopardy in which the medical gentlemen had been placed, and considering that there was a great public question raised as to the use of water-gas, the Coroner thought it his duty to lay the matter before the Home Office authorities; and as there was not time to communicate by letter, Mr. Malcolm proceeded to London on Friday night. On Saturday forenoon he had an interview with the Home Office officials, who called in Dr. Stevenson, of Guy's Hospital, for consultation. The importance of the case was recognised, and Dr. Stevenson was instructed to attend to the analysis; and inasmuch as the delay of the *post-mortem* examination had caused certain difficulties, it was thought advisable that Dr. Stevenson should proceed to Leeds, to attend the examination of the bodies. That gentleman accordingly accompanied Mr. Malcolm to Leeds on Saturday evening. If it should be established that the deaths of the unfortunate men have been caused by water-gas, we understand that the Home Office will then consider what assistance they should give, in connection with the Board of Trade, either at the inquest, or by taking the matter up afterwards, to have a thorough investigation into the question.

The *post-mortem* examination was resumed on Monday morning at ten o'clock, and was concluded about half-past two. All the medical gentlemen named above were present, with the exception of Mr. Arthur Scattergood. In the presence of the Coroner, the band-room was unsealed, and the bodies were removed to the tent, where the examination was conducted without any repetition of the experiences of Friday. Dr. Stevenson removed a portion of the viscera for analysis.

VI.—DISEASES OF WOMEN.

The Management of Abortion (New York Academy of Medicine, *New York Medical Journal*).—Dr. Murray deplored the principles which guided the general practitioner in the management of abortion cases. The result was often disastrous to the woman, for an abortion too frequently ushered in a whole series of uterine troubles—hæmorrhage, salpingitis, barrenness, subinvolution, and so forth. Abortion was always a pathological process. The muscular coats of the uterus were still undeveloped, and contractions were inefficient. The cervix did not relax readily, and involution was but slowly accomplished. Goodell had likened abortion to the plucking of immature fruit. Two symptoms were always present—pain and hæmorrhage. The speaker then went on to describe the symptoms of threatened abortion, in the treatment of which he advocated opium for the pain; extract of viburnum prunifolium would be of benefit, and chloral hydrate or the bromides, given by the mouth, seemed to contribute to the cessation of uterine action. Careful examination should be made to ascertain the exact condition of things, and whether the symptoms were really referred to threatened abortion or to some other cause. The appearance of regular menstruation was possible up to the second month, though not thereafter. If an escape of waters or membrane had taken place, then efforts at prevention should give way to others in the direction of hastening the process of abortion. Thorough and persistent antiseptic precautions should be maintained. The vaginal canal should be tamponned with gauze, well applied around the cervix by means of an applicator, the patient being placed in Sims's posture. If the bleeding was very profuse alum might be used on the first tampon. Tampons were to be preferred to the colpeurynter. If the os was found dilatable, but not dilated, ergot might be given in small doses. When the tampon was removed the os was generally found to be sufficiently dilated to admit of the ovum being reached by the forefinger. It was better to empty the uterus. Examination of the endometrium should be carefully made, and if the membranes were found detachable they should be removed with a placenta forceps. If portions still adhered, the blunt curette of Thomas should be used to remove these fragments.

The operator should not be satisfied until the whole endometrium was freed from projections. The cavity should then be washed out with carbolic-acid solution of the strength of 1 to 100, a reflux catheter being used. The hæmorrhage would cease entirely as soon as the uterus was clear. If the uterus had been depressed during the examination it was most important that it should be raised again. In cases of neglected or of incomplete abortions great care should be exercised. It was important that everything which had been preserved should be examined. If the membranes had not been made away with they should be approximated to determine their entirety. Examination should be made of the cervix and the endometrium should be explored. When the speaker was able to see what had been passed and it seemed complete, he simply ordered antiseptic vaginal washes with antiseptic dressings to the vulva, and made careful inspection of the cloths removed each day, watching also for any local abdominal tenderness or rise of temperature. In neglected cases where the patient showed evidences of septic trouble all authorities agreed that the cervical canal, if closed, should be dilated, the cavity thoroughly washed out, and the curette used. The general septic symptoms should be combated by the administration of alcohol, quinine, and generous food. It was said that the galvanic and faradaic currents possessed a certain antiseptic action, but the speaker had had no experience with the method. He did not favour the use of the brush as advocated by certain French obstetricians, but thought the blunt curette would be found to answer all requirements. Subinvolution might be averted by the judicious use of ergot. Abortion and miscarriage were fertile sources of a train of supervening uterine troubles, and the proportion dying from septic complications after miscarriages was greater than that of the deaths by sepsis after labour at term.

Dr. A. F. Currier thought that the method of treatment in abortion cases was one which had reached something like exactness. This was largely due to the advances made in the use of antiseptics. He was glad that such stress had been laid on the value of the blunt curette in diagnosticating the condition of the endometrium after the expulsion of the fœtus. It was much more reliable and more easily used than the forefinger. It was his rule to apply pure carbolic acid over the entire mucous membrane of the uterine canal, so that anything missed by the curette might be reached by the acid. He obtained good results from this method. There might be conditions, as, for instance, after prolonged and profuse hæmorrhage, when interference at the time would be contra-indicated, in proof of which he cited a case from his own practice. Dr. Murray had spoken of tamponing the vagina, but had not mentioned including the uterus. The speaker, however, advocated this plan, and believed it facilitated the expulsion of the fœtus.

Dr. Paul F. Mundé said that in 1883 he had written a paper advocating the immediate removal of the secundines after abortion. This article had elicited a great deal of criticism because of the very positive views which it contained. Whenever he had to deal with a case in which abortion was imminent and unavoidable he would endeavour to save the woman loss of blood, and at the same time would hasten dilatation of the os by tamponing the vagina with iodoform gauze. This might be removed in twenty-four hours and replaced if required. Sometimes it might be necessary to dilate the external os. For this purpose tupelo tents could be used, two or three of which might be introduced, though it was now easy to get them large enough to allow of the introduction of one or two fingers after dilatation. When the

canal was sufficiently wide to admit of the procedure he would introduce his finger and remove the contents of the uterine cavity as thoroughly as practicable. He would endeavour to keep the ovum intact if the membranes had not already ruptured. He much preferred to empty the uterine cavity at one sitting whenever this was at all practicable. The class of cases for which he was usually called in consultation was that in which hæmorrhage, chill, and high temperature had already occurred. He generally found the canal sufficiently widely dilated to allow of the introduction of a finger, and even if this were not the case it was not difficult to open it. The finger once passed into the uterine cavity, the rest was easy, requiring only care and persistence in clearing it of its contents. He had always advocated this course, and it was still his firm conviction that a woman who retained within her uterine cavity any portion of a ruptured ovum was in danger of two accidents —first, hæmorrhage, severe and sometimes fatal; and, second, septicæmia. To those who urged the most extensive experience of cases in which the retained portions of the ovum or secundines had been allowed to take care of themselves he would say that, in spite of this experience, those gentlemen would surely some day come to grief. Nature would do a great deal, but it was not wise to let nature handle these cases too long. He differed with the last speaker, who thought that the curette was better than the finger. With an instrument it was impossible to determine that the cavity was really empty. He preferred to give the patient a little chloroform, and then, passing the exploring finger up to the fundus uteri and compressing the abdominal wall with the disengaged hand, he could determine accurately the condition of the cavity. Then a curette might be introduced and everything cleared away, when the finger should again be introduced. If it was ascertained that the work had been thoroughly done, then the patient might be deemed practically safe. He had yet to meet with a case in which he could regret having conscientiously followed out this plan. He would never use more force than was justifiable, and would always be careful not to subject his patient to an injury more severe than that of leaving the uterus alone. The steps he had indicated were such as he always followed, unless the contra-indications were urgent and obvious—for instance, when the woman was very low and where temporising was the only safe thing to do until she could bear interference. The speaker then described the various curettes and placental forceps which he found most useful, and went on to say that as soon as the uterine cavity was thoroughly clear he introduced a double-current catheter and passed in a stream of hot two-per-cent. carbolised water. He never introduced corrosive sublimate within the uterine cavity. He had always feared toxic absorption from its use. After the cavity was washed out the uterus invariably contracted, and there would be no further occasion for any local treatment, except perhaps in a few cases an uterine injection for a few days. He wished to be understood as saying that he was not at all afraid of criticism on this subject. He was constantly reading in the journals about letting nature take care of these cases. He deemed it far wiser to give nature all the assistance possible in this particular. It had been urged that the procedure was unsafe at the hands of inexperienced men. If the practice was admitted to be sound in theory, then it was imperative that the inexperienced men should acquaint themselves with the requirements, and it was for such purposes that post-graduate schools were instituted. When it was necessary to induce abortion, as in cases of uncontrollable vomiting or fibroid in the pelvis, he found it best to introduce tupelo tents frequently, until the os would allow the finger to pass, and then, when the uterine canal was thoroughly dilated, the ovum might be gently detached by sweeping around the fundus uteri with a blunt curette, when it could generally be removed almost entire.

Dr. Fry, of Washington, was then asked to speak in reference to the use of electricity in the class of cases under consideration. He said that its use was not indicated in imminent abortion, but rather in neglected cases where the fragments of placental tissue remained in the uterus and produced hæmorrhage or septic symptoms. The faradaic current was to be used only during contractions with a view to increasing them. He did not think this current capable of inducing them. He had used the galvanic current for its coagulating effect. The positive pole was considered antiseptic as it eliminated oxygen and chlorine. The latter was frequently given off in such quantities that it might be detected by its odour. He had been conducting some experiments as to the chemical effects of the electric current upon micro-organisms, but at present he was not able to give any results, as there had been some inaccuracy in the technique incident to the initial observations.

Dr. H. J. Boldt thought the subject of abortion was very well understood theoretically but not practically. It was his experience to be called to cases where the first principles of antiseptic precautions had generally been entirely ignored or neglected. He thought a 3 per cent. solution of carbolic acid hardly strong enough to use as an antiseptic, and the solution itself not so good as the bichloride. He never failed to make use of the finger for purposes of examination, and he urged it as a plan to be adopted in every instance. He, however, deprecated the employment of too much force where portions of the uterine contents still remained closely adherent. So long as they were not disintegrated and remained attached, he thought it unnecessary to interfere with them, as they would be dislodged in the course of time.

The discussion then became general, and was closed by some brief comments by the author of the paper.

A Successful Case of Laparotomy and Supravaginal Amputation of the Uterus for Rupture.—Dr. Henry C. Coe read a paper with this title. On September 8th, at 1 p.m., he was called to a desperate case of labour to perform Cæsarean section. The patient was a healthy Irishwoman, twenty-three years of age, with a rapid, feeble pulse, and evidently in a state of collapse. The gentleman in attendance had feared that rupture of the uterus had taken place two hours before. Examination of the abdomen revealed two tumours—a larger one filling the right side of the abdomen and extending as high as the ensiform cartilage, and a smaller one occupying the left iliac fossa —both firm and unyielding. It was evident that the former was the body of the uterus tilted over to the right and in a state of tetanic contraction, and the latter the head of the child. Palpation of the abdomen above the latter gave an ominous gurgling sound suggestive of free fluid in the peritoneal cavity. Prolonged attempts had been made to extract the child by forceps and version. With the introduction of the hand into the vagina the discovery of laceration of the anterior lip of the cervix antero-posteriorly and a laceration through the vaginal junction on the left side was made. The finger, passed through the rent, entered the abdominal cavity. The child, which was unusually large, was dead, presented in the left dorso-anterior position with the right hand and foot prolapsed, and was firmly impacted, the head seeming to be partly outside the uterus. Believing that a further attempt at version would only extend the tear, he at once decided that laparotomy offered the best chance of saving the woman. The patient's condition was desperate, and the surroundings were such that any approach to antisepsis would be impossible. She lost a large amount of blood, and her pulse was so feeble that hypodermic stimulation with brandy and ether was resorted to. A free incision, eight inches in length, was made through a very fat abdominal wall and into the peritoneal cavity, which contained a quantity of fluid blood and clots. A rent was found extending upward from the cervix through the left broad ligament half way to the fundus. The head of the child lay in the left iliac fossa outside of the uterus, being grasped by the edges of the tear. It was at once seen that this would not be a case for suturing the uterus, as arterial hæmorrhage was going on from the vessels of the lacerated broad ligament. As no time could be lost, the uterus was turned out of the cavity, the cervix constricted by a piece of rubber tubing cut from a fountain syringe, the écraseur having been forgotton in the haste, and the child extracted through the tear. Without waiting to remove the placenta, the tubing being secured with an artery forceps, the uterus was excised, together with the ovaries and tubes, and all bleeding vessels were tied. This part of the operation was completed in twelve minutes. The utero-sacral ligament on the right side had been also badly lacerated. After securing the vessels and sewing the torn peritonæum with a continuous catgut suture, the peritoneal cavity was thoroughly irrigated with hot water and the stump secured in the wound with knitting-kneedles. No drainage-tube was used. The bladder was examined and found apparently uninjured. The cervix had been so badly torn that it was subsequently sloughed out. The patient rallied well, but had a pulse of 140 to 150, and no hopes had been entertained of her recovery. From the outset she was free from nausea and able to take stimulants. On the second day her temperature had risen to 102° to 103° F., and there were general abdominal tenderness and distension, but, by maintaining free catharsis and using the ice-bag, peritonitis was aborted. The urine was drawn for the first four or five days. The stump quickly necrosed; and on the fourth day the tubing was replaced by a Kœberlé's serre-nœud. The entire mass was removed by the end of a week, and the cavity packed with iodoform gauze. The patient had taken nourishment and stimulents freely, but her pulse had remained at 120, and her temperature had risen every evening to 101° to 102° F. At one time an exhausting diarrhœa had threatened her life. She complained of no pain, but suppuration of the hæmatocele which had formed in the left broad ligament was feared. Early in the second week the urine began to escape *per vaginam*, although the patient could retain it to some extent. A careful examination with the finger and speculum showed that a cervico-vesico-vaginal fistula had been established, and that there was considerable sloughing of the upper portion of the vagina. All the necrosed tissue at the bottom of the abdominal wound was picked away, until nothing remained of the cervix but the portio vaginalis. The wound granulated satisfactorily, but there was a free communication with the vagina through which

urine and the douche water sometimes welled up. She was allowed to get up at the end of the fourth week. The fistula was still patent, as the urine still dribbled away, but not so freely as at first. At the end of the fifth week the abdominal wound has entirely closed. It was hardly necessary to add that the after-treatment of such a serious case in a dirty tenement-house had required constant vigilance or the patient would certainly have succumbed to the operation or the subsequent complications. Before commenting on the case it was important to classify it. Dr. Robert Harris, of Philadelphia, had clearly pointed out that it was neither a Porro nor a Cæsarean section proper, but an operation *sui generis*. Prevôt, of Moscow, had reported the first case, an unsuccessful one, in which the ruptured uterus had been excised after removal of the child through the rent without previously incising the organ. There had been ten true Porro-Cæsarean sections for rupture of the uterus in this country, four of the women having been saved. Dr. M. Price had reported a case in which an operation very similar to the speaker's had been performed last April, but with a fatal result. In conclusion, the speaker said that, given the same conditions, he would adopt precisely the same method of procedure in another case of rupture of the uterus, because he believed that it offered the best chance of saving the patient, for the following reasons: 1. That this operation could be performed in the shortest possible time. 2. That it was impossible to properly suture such an extensive rent, with contused edges, as the one described. There was also imminent risk of hæmorrhage after removal of the temporary constriction. 3. Where prolonged use of instruments without antiseptic precautions had occurred, the interior of the uterus was sure to be so badly contused that subsequent danger of sepsis was great. The additional shock to the patient from removal of the lacerated uterus was preferable to the exposure of septicæmia, which would certainly follow by leaving it. 4. The objection made by Dr. Harris that a cervix split by laceration could not be very well fitted for constriction, as the part below the wire might discharge septic matter into the abdominal cavity through the rent, was a good one. But the writer thought, if the tear in the peritonæum was carefully closed and the stump properly constricted and shut off from the peritoneal cavity, that there was less danger than in trusting to the suture alone without constriction. Finally, with due respect for the opinion of such a weighty authority as Dr. Harris, who believed that it "would hardly be admissible" to subject a woman with a normal pelvis to "the unsexing operation of removing the lacerated uterus with the ovaries, as was done by Prevôt," it should be borne in mind that the surgeon was sometimes called upon to do so, and to do at once, what he believed was the best thing for the patient without regard to established precedent or even to the ordinary rules of surgery.

Carcinoma of the Uterus and Ovary.—Dr. A. Palmer Dudley read a paper with this title, and presented some pathological specimens. He said the growth had been removed from a patient fifty-one years of age, of Irish birth, whose occupation had been that of a domestic servant. Her family history was good. She had been married twenty-eight years, and was now a widow. She had borne two children and had suffered one miscarriage since, due, she had said, to lifting a heavy weight. She had been operated upon several years before for some form of uterine trouble; just what it had been could not be learned. From that operation up to within three years she had been perfectly well. The patient had said that within the last three years, the exact time she could not remember, some sort of tumour had broken in the pelvis, and that a large amount of blood had come away. This had been followed by repeated floodings which generally had yielded to treatment. She was admitted to Randall's Island Hospital on November 13th, 1888, into the service of Dr. McLean. Digital examination showed the uterus to be large and the os patulous. Quite a large tumour of firm consistence, probably fibroid, was found to lie above and to the right of uterus; the growth moved with the uterus. A curette was used and a large amount of villous tissue removed, which had the appearance of a cast of the uterine mucous membrane. The speaker could not learn whether there had been a microscopical examination of this tissue. The possibility of malignancy had been noted and recorded in the history book. The hospital service had changed and she had come under the speaker's care on February 1st, 1889. He proposed to operate for removal of the growth, but the patient would not entertain the idea, and left the hospital February 3rd. She had not been seen again until September 23rd, when she reappeared at the hospital and begged for the operation for her relief. During her absence she had suffered from repeated hæmorrhage. Further examination revealed an increase in the growth to the right of uterus, but the latter seemed to have remained of about the same size. The passage of the finger through the external os revealed a growth presenting, which had the feel of submucous fibroid. There was no odour about the parts that were unnatural. Pain was absent, there was no cachexia, and, in fact, there were no objective symptoms of malignant disease. The speaker made a diagnosis of subperitoneal and submucous fibroid, and proposed suprapubic hysterectomy, as the growth was too large to remove *per vaginam*. On October 4th, 1889, he performed a modification of Schroder and Bantock's operation, which he had designated previously as the intrapelvic, but extraperitoneal, method of treating the stump in hysterectomy. After the uterus and such of the structures as had been involved by the morbid growth, including the vermiform appendix, had been removed, the mass was submitted to a pathologist for microscopical examination, and a diagnosis returned of epithelioma of both uterus and ovary.

Dr. Coe, by means of a black-board illustration, depicted the steps of the operation he had performed, demonstrating thereby the all-important factor that the completed closure of the various incisions left no ligatures in the pelvic cavity, that if pus formed it would be outside the cavity of the pelvis, and that perfect drainage could be effected through the os uteri externum.

Ectopic Gestation (*Medical Journal*, New York).—At a meeting of the Philadelphia County Medical Society, held on October 23rd, Dr. Mordecai Price read the following paper:—In bringing to the notice of this society the much-discussed subject of ectopic gestation, my hope is not so much to advance anything new as to make plain our duty and manner of procedure in these desperate conditions. Bernutz and Goupil, of France, and Parry, of our own country, did much to advance our knowledge on this subject, but it remained for Mr. Hallwright to bring it forcibly to Mr. Tait's notice in one of his patients, in whom he had diagnosticated ectopic gestation, and urged operation. "The suggestion staggered me," says Mr. Tait, "and I am ashamed to have to say I did not receive it favourably." A second hæmorrhage killed the patient. A *post-mortem* examination revealed the fact to this great leader in abdominal surgery that Mr. Hallwright was correct in his conclusion, and that the patient could have been saved. An opportunity was soon offered in Dr. Dolan's, of Halifax. Dr. Dolan had also diagnosticated ectopic gestation, and given as his opinion to the husband that nothing but an operation would save the patient's life. He telegraphed for Mr. Tait, who not only agreed with him, but had the requisite daring to operate, to save the patient, and revolutionise the whole treatment of extra-uterine pregnancy. I leave it to you, gentlemen, to judge to whom the greater amount of credit is due to the practitioner who urged it, or to the illustrious surgeon who performed it.

A pregnancy, as we all know, should be within the uterine cavity, and the only other place is primarily in the tube. That this condition may be possible, the tube must be diseased, its lining membrane removed, its ciliated epithelium no longer urging the product of conception onward to its natural abiding place nor retarding in the least the spermatozoa from intruding on dangerous and forbidden ground. This condition is brought about, I believe, in 50 per cent. of the cases by gonorrhœa, and in the remainder by cold, septic conditions following childbed, and catarrhal affections from other causes. That the pregnancy in the beginning is always tubal, I think is well proved, from the fact that the tube is the only portion outside the uterine cavity offering the conditions favourable for impregnation. The product of conception thrown into the peritoneal cavity either at the time of inpregnation or during the first few weeks of gestation would undoubtedly be digested. We have the best proof of this in the fact that in early ruptures into the peritoneum of only a few weeks no fœtus can be found; only the blood clot, the diseased tube, and membrane remaining. Those cases that have advanced to maturity in the peritoneal cavity have, without doubt, been those first developed in the tube, and then ruptured into the broad ligament, and, when able to resist the digestive fluids of the peritonæum, the secondary rupture has taken place.

We may pass over the other forms of so-called ectopic gestation, for, if they ever occur, it is so rarely that they do not deserve our consideration. Tubal pregnancy would be of but little moment to us if it were not for the fact that most patients are not aware there is anything wrong. If they suspect pregnancy at all, they have no reason to doubt that it is of the usual old-fashioned kind, and the first warning, alike to patient and doctor, is rupture of the tube, with symptoms of internal hœmorrhage—often so serious that the patient lives but a few hours. These cases are far more numerous than you would suppose - in our city alone, from all sources, about twenty-five a year; and when you remember that five year ago the mortality was 100 per cent., and now at least 90 per cent. are saved, but we have too much to be thankful for to Mr. Tait and his adviser, Mr. Hallwright.

The symptoms of ectopic gestation before ruptured are of a vague and uncertain character. Those best qualified to properly interpret them, whose experience in such conditions has been greater than any other investigators', have yet to see one and recognise it before rupture. The only reported cases said to have been recognised and treated before rupture have been in the hands of our electrical friends and enthusias-

tically dwelt upon, and the man who would treat them with a knife has been given a back seat and denounced in unmeasured terms for his mutilation of the poor woman when it was so easy to get rid of the product of conception by so safe a plan as the electrical current. But we find by investigation that in many of these reported cases there was little foundation for the belief that the women were pregnant. Some of them have fallen into the hands of other men and been operated on, and no pregnancy existed. And I cannot but think the others could not bear investigation requisite to a proper diagnosis.

The symptoms after rupture are sufficiently plain and urgent to warn any earnest medical man of the patient's condition. They are as plain as any other surgical affection and more imperative than most. In a woman who has been sterile for a length of time, it may be for years, whose period has been delayed for two or three weeks or longer, after slight exertion or lifting some heavy object, there occur agonising pelvic pains and collapse, followed by all the symptoms of loss of blood. If the patient reacts, this followed by recurring pain and collapse, constant uterine hæmorrage, it may be with small loss of blood, discharges loaded with shreds of decidua, leaving the impression in the patient's mind that she has had a miscarriage. There are pain and fulness on the side of rupture, with a mass of a boggy, fluctuating consistence in the pelvis. No one case being a repetition of any other, there is nothing fixed and unchangeable, save the termination—death, almost without exception, unless prompt surgical aid is given. I know no better place than just here to call your attention to the terrible mortality of the past. All of Bernutz's reported cases ended fatally. Dr. Forman, the coroner's physician, in a letter to my brother, reports nineteen cases of death from hæmorrhage from rupture of tubal gestation sacs. All ended fatally in six hours but one. How differently this list compares with that of many operators! All have recovered, save a very small percentage, from the surgical treatment in the hands of these operators.

There are many conditions that may be confounded with extra-uterine pregnancy. In fact, any mass in the pelvis, such as tubal trouble, a small ovarian or dermoid tumour, hæmatocele from traumatism, an abscess of the tube or ovary, gonorrhœal pyosalpinx, all have been mistaken for extra-uterine pregnancy. Even our electrical friends have mistaken tubal trouble for extra-uterine pregnancy, and wasted many valuable sittings to kill the fœtus, where none existed, and, strange to say, they did not cure the diseased tube. How, then, Mr. President, can we ordinary mortals come to a positive diagnosis? But these mistakes of diagnosis are of small moment, as the conditions which could be mistaken for extra-uterine pregnancy should be removed by the knife. I have seen the abdomen opened several times when a positive diagnosis had been made, where no pregnancy existed, and a small pus tube or dermoid tumour instead. I am sure the operator was not greatly disconcerted by the coditions found. No one need give himself anxiety; he should feel sure before operating that whatever the mass is, it must come away. In most cases of ectopic gestation in our own hands the diagnosis was made before operation. Rupture had taken place in every case. Diagnosis of tubal pregnancy before rupture would simply be a happy guest. Hæmatoceles, that have given our predecessors so much trouble, I think can be credited in great measures to ectopic gestation, and the remaining small number to traumatism.

We have come to that period where experimental treatment of ectopic gestation is a disgrace to our profession. Electricity, with all its barbarous instruments and murderous delays, will, I hope, ere long be forever thrown aside as a means of treatment for this condition. Its history certainly does not offer to any thinking mind any proof of its value, while, on the contrary, its record of death is truly appalling. Puncture, or injections into the sac of morphine or any substance, with the hope of killing the fœtus, is attended with greater risk to the mother than an immediate operation for its removal. I can find no language strong enough to express my commendation of these experimental methods.

Operation.—Where there is time, the room should be thoroughly cleaned, and all needless articles of furniture removed. A most efficient cleansing of the body with soap and water and brush is necessary, and the bowels should be thoroughly evacuated. No antiseptic should be used. If possible, a trained nurse should be obtained—one who is accustomed to the work of the operator, able to cleanse and take care of a drainage-tube and encourage the patient to bear patiently with the discomforts necessarily following an operation of this kind. Opium must be positively forbidden in all abdominal work; it interferes with the secretions, sickens the patient, makes her irritable and hard to manage, and conceals the symptoms of danger and otherwise complicates the recovery. A good light is needed. Every instrument and ligature and suture should be carefully scalded and placed in trays of warm water, handy to the operator or his assistant, so that in case of any emergency there will be no delay, for time is a material factor in these operations. The shorter the operation the less the shock. It should be mimimised in every detail; short incision, careful enucleation, perfect tying, most through irrigation with warm distilled water. No antiseptic whatever has any place or purpose in this operation. Antiseptics have done bad work for good operators. We see this admission in the journals almost daily: "Perhaps the antiseptic was too strong." Chemical antiseptics of any kind in the peritonæum do murderous work, and should be abolished by law, if our surgeons have not sense enough to discard them in this department of surgery. The after-treatment in these cases is of great importance. The drainage-tube should be cleansed every half-hour for the first day or two, until the discharge becomes small in quantity and serious in character, when it should be removed. The contents of the bowel should be kept in a soluble condition; and it should be purged with Epsom salts upon the slightest indication of peritonitis, when the symptoms will disappear like magic. The patient should be kept in bed from three to four weeks in the most favourable cases, and longer if deemed advisable. Any member of this society may be called to do this operation without preparation, instruments or nurses, and I have no doubt you would meet all the requirements of the case possible under the circumstances. With a patient bleeding to death, you cannot wait for anything. Where the surroundings and the condition of the patient will admit, an operator of known skill and courage should be procured.

VII.—SURGERY.

TREATMENT OF INGUINAL AND FEMORAL HERNIA.[1]

BY W. C. BRAISTED, PH.B., M.B.

Mr. President and Gentlemen of the Academy: The subject which I wish to bring to your notice to-night is one in which I have taken a deep interest for some years, and while I take pleasure in availing myself of such an opportunity, yet on account of the importance of the subject, the immense amount of literature already existing, the prominence and experience of fellow practitioners who have devoted so much time and attention in its study, one may well hesitate before speaking with any degree of confidence.

It is not my intention to criticise or to compare the views of others in regard to the operation in question, but simply to call attention to the importance of the subject, and especially to give a detailed description of a simple procedure, which seems to have partially solved an unsettled question, and which appears to have a logical foundation for its support. Without further apology let us then proceed to the consideration of the subject of "The Radical Cure of Inguinal Hernia, with some brief Remarks relating to Femoral Hernia."

In regard to the importance of the subject, when we consider that, according to the statistics of various authors, from 1 in 3 at a minimum, to 1 in 7 as a maximum, percentage of the human race suffer from some form of hernia, we immediately find a wide and fruitful field before us, and an opportunity, if we should be successful, of doing an immense amount of good to our fellow man, and of relieving what often has been the source of life-long care and suffering.

From the earliest times, this problem has confronted the surgeon, and as often as carried away by enthusiasm over a supposed triumph, so often each and every one has at last proved more or less a failure. Concerning these methods, we may sum up as the result of hundreds of years of study, the following as worthy of mention:

1. External appliances, as ointments, plasters, injections, cauteries, trusses, etc.

2. Simply incision, returning the intestine and closing the external abdominal ring.

3. Attempts to plug the inguinal canal by:
a. Simple sutures.
b. By inverted sac.

c. By excision of the sac and plugging the canal by omental, connective, or other adventitious tissues at one's command.

d. By simple incision of the roof of the entire canal, and causing the inguinal canal to be filled by new granulation tissue—in other words by the obliteration of the canal.

It is concerning the last of these of which I wish to speak. This operation is rapidly coming into favour and prominence among surgeons generally, especially in New York, and the credit undoubtedly belongs to Dr. Charles McBurney, who accidentally hit upon and perfected it, and who has also a brilliant record of thirty-six cases. It is, however, but just to mention that Reisel, many years before, performed an operation much the same in character, but the value of which seems

[1] Paper read before the Detroit Academy of Medicine, October 6th, 1889.

not to have been appreciated. I myself stumbled upon the idea while doing a secondary operation on a case previously operated upon by a brother practitioner, after the manner of MacEwan, which had failed. I, however, found that Dr. McBurney had been doing the same for some time.

CONSIDERATION OF THE PROBLEM OF HERNIA.

In considering an operation for inguinal hernia, our problem seems simple. Briefly it is:

1. Two openings, the external and internal abdominal rings.

2. A connecting canal, the inguinal canal.

3. A wedge-shaped mass of omentum, peritoneum, and intestine, tending to dilate this canal and its openings, and driven by the combined pressure of the abdominal contents and the muscular wall of the abdomen, which is estimated at a power of 50 to 75 lbs.

4. The tendency of this combined pressure is to expend itself at this point where the peritoneum has lost its normal shape, presenting, as the sac does, an infundibuliform wedge.

To cure, we must remove the above-mentioned conditions, *i.e.*:

1. Restore the peritoneal cavity to its normal size and shape.

2. Having done this, the force of the pressure of the abdominal contents is no longer expended at a single point by a resolution of forces, but *is* expended equally on each square inch of peritoneal surface.

3. To present this uniform resistance to the abdominal forces, we must destroy the possibility of, or even the tendency to, the formation of the sac wedge; *i.e.*, we must obliterate the inguinal canal.

4. We must remove the tissue forming the wedge itself, *i.e.*, the infundibuliform sac, which if left behind, either after being returned to the abdominal cavity, or left as a plug in the inguinal canal, results in the one case in destroying the normal symmetry of the peritoneal surface, and in the other, by constant pressure and imperfect adhesion and agglutination, atrophies, and leaves in the end the same condition which we have tried to remedy, and the possibility and probability of a return of the hernia.

If the inguinal canal is in fact destroyed, how then is it possible for the return of the hernia?

If the inguinal canal is necessary for the condition producing or tending to produce hernia, how if there is no inguinal canal, can a hernia occur? Here then lies the supposed solution of the question, and it appears so simple, so straightforward and plausible, that there is left no room to doubt. But here we are not left entirely to theory; of Dr. McBurney's thirty-six operations, each has been a cure without bandage, truss or other support; of thirteen operations for hernia, of my own (7) have been of this kind, and all have resulted in permanent cure, no truss or other support being required. Here then are forty-two consecutive cases, without a death, and without complications. Surely this would seem to warrant at least a slight hope that the operation may perhaps be the long sought-for solution of the question.

The operation, in my experience, is applicable to any inguinal hernia; the largest scrotal herniæ of long standing have proved as amenable to treatment as the smallest and more recent varieties. The cases have been unselected, and for the most part have been herniæ of large size and long duration, and with each case the conviction becomes stronger that the operation meets every indication. Time, the only test that can render us secure in one position, has been so far the only element of uncertainty, and for that reason one must still maintain an expectant and perhaps doubtful attitude. My first case has stood the test of some two and one-half years, and the patient, when last heard from, was loud in his expression of satisfaction at the result.

But it is of especial importance to recognize the fact, that if we have at last a sure and secure method of dealing with this trouble, we are immediately relieved of any hesitancy or doubt, when brought face to face with the perplexing question of what to do with strangulated or partially strangulated hernia.

Probably no one here but can call to mind some case of his own or friends, where the dangerous plan of taxis or expectancy, carried beyond safe limits, has resulted fatally. The teaching of the text-books at the present day leaves one in a sad condition of uncertainty as to his mode of procedure in a case of sudden and apparently irreducible hernia. Having failed in taxis we are to wait, to elevate the extremities, make hot or cold applications to the tumour, sleep over it in fact, in the uncertain hope that somehow or other the trouble will disappear of its own accord. In the meantime, who can foretell the result; perhaps a favourable one; perhaps the hernia hidden in its numerous coatings, and pressed upon by the constantly descending fæces and intestinal contents, is gradually having its very life squeezed out, and with it the life of the unhappy patient. The best surgical dictum of to-day says: "Any hernia not reduced in twelve hours, should be opened and reduced." But if we can find a method which offers a certain cure and no risk to the patient, we should no longer hesitate, but, secure in our position that by operating we can do nothing but good to our patient, we can calmly set about our task with a feeling of security, the pleasure of which only one can realise who stands confronted by such a problem. One of the saddest things to contemplate in medicine, and one which to-day tends to relegate medicine to an uncertain standing as an exact science, is the fact that we have been able to make so few laws for our guidance in regard to which there can be no dispute, no doubt, no uncertainty. If in the future it shall be found that we have in this instance been able to make such a fixed and definite law as the following: "That in every case of inguinal hernia, conditions being favourable, we should operate," we shall have accomplished a great end, and placed medicine quite a few steps higher in the scientific ladder.

OPERATION BY THE OPEN METHOD.

Having thus briefly indicated the somewhat extended scope of the operation, let us now consider the operation itself. Here, as in all operations of like magnitude, we must remember that success depends to a great degree upon our care in attaining asepsis.

With sepsis the operation becomes a very serious matter, and the possibility of a fatal termination is always to be borne in mind.

I think it is always well, on every occasion, to run over the preliminary antiseptic precautions in every case. Antisepsis thus becomes a part of one's self, and the surgeon performs every operation in a perfectly aseptic method from mere force of habit, and without any necessary thought or concentration of mind upon the details of aseptic procedures. The operation should be performed if possible on a clear day, in the morning, the patient's bowels having been emptied early, and a glass of milk or other light nourishment taken. The patient, being placed upon the table, rendered aseptic by washing and covered by towels soaked in bichloride, 1-1000, should be well protected over the chest and extremities. The temperature of the room should be, if possible, about 80° Fahr. The region of the thighs and lower half of the abdomen should be thoroughly washed and scrubbed with hot water and soap; the hair of the pubes and scrotum carefully removed by a sharp razor; the remaining fat and dirt of skin should be carefully removed by washing the seat of the operation with ether, and the parts should be carefully washed and irrigated for some few moments with a warm solution of bichloride of mercury, 1—4000. The thighs should be carefully wrapped in bichloride towels, 1—1000, and the surroundings of the contemplated operation by same; one or two carbolised towels should cover the blankets on the chest upon which instruments in immediate use can be deposited.

The instruments and other appurtenances should be carefully prepared—and I think it always wise to carefully boil all instruments to be used. All appliances for operation having been carefully prepared, our patient ready for operation as described, the surgeon and his assistant in position, the anæsthetic, preferably ether, should be given. In every case I personally prefer, if possible, that the hernia should be well down and held securely by an assistant.

When the patient is fully anæsthetized and quiet, having carefully settled upon the direction of the axis of the canal, the skin being rendered tense, an incision extending from $\frac{1}{4}$—$\frac{1}{2}$ in. above the internal ring, to $\frac{1}{2}$—1 in. below the external ring is made—the first incision simply penetrating through the skin; next with light, full strokes the fat and fascia are divided. From this point the greatest caution should be exercised in approaching the sac. A small blunt grooved director is passed gently under each layer of hernial covering, and on this the tissue slit up to the full extent of the wound. Too much time and care can hardly be spent in the careful dissection of the sac. Having reached the sac we come to the first important question of the operation, viz., how to treat it.

1. *In recent herniæ* of small or unappreciable size, when the peritoneum has not been permanently stretched in a pouch, I am inclined to simply return the mass to the abdominal cavity.

2. *In heruiæ of longer standing*, and with permanent dilatation, and especially in hernia of large size, the sac should always, I think, be carefully opened at or near the fundus. The glistening coat of intestine is easily recognised, and should gently be returned to the abdominal cavity beyond the internal ring, the finger being kept in the sac to prevent its return; then a catgut ligature, No. 8 best, of the aseptic properties of which we can have no possible doubt, is passed around the sac and slipped just beyond the finger end and just inside the internal abdominal ring, tightly tied by a triple knot, and the sac cut off as near the knot as safety warrants. We have now practically completed the operation. Let us recapitulate:

We have cut through and destroyed the entire roof of the inguinal

canal; we have destroyed the external and the internal abdominal rings; we have restored the peritoneal cavity to its normal size and shape.

One very important factor, seldom if ever dwelt upon, is the care to stop all hæmorrhage, be the oozing ever so slight. In two cases I have been extremely annoyed by the slight and continual oozing of blood into the connective tissues surrounding the wound, and into the scrotal tissues below, in one case being obliged to undo the dressings and cut away much black, infiltrated, and swollen tissue, and this too when I had used great care, as I thought, to limit all hæmorrhage.

This oozing is especially liable to occur in those cases of enormous scrotal hernia where the sac has become firmly adherent, and where much tearing of scotal tissues ensues from endeavours to free the sac.

I may mention here, that in the last case operated on, the one presented to you, I succeeded in not cutting any vessel of size, nor was I compelled to apply a single ligature, not more than a few drachms of blood escaping during the entire operation.

In completing our operation, I have, as a safeguard, began by fastening the cut internal end of the sac to the tissues around the internal ring by means of a few sutures; this also prevents any subsequent discharge from entering the abdominal cavity, and so tends to seal the most delicate tissues involved from further septic exposure.

The next point to which we pay particular attention is the spermatic cord, which you will remember lies along the inner border of the wound, and which with its vessels is quite exposed. It has been my custom to carefully stitch by continuous sutures that there shall be no undue pressure on the cord itself, thus leaving the latter in a snug little compartment by itself.

Next the outer flap is loosely stitched to the bottom of the canal, no attempt being made to approximate the edges of the wound; on the contrary the idea seems to be to leave as much space as possible between them, to be filled subsequently by new granulation tissue. If the scrotal tissues have been much disturbed, as in the case of large adherent sacs, it is well to run a small rubber drainage tube through the bottom of the scrotum thus securing egress for any possible collection of inflammatory material. The wound itself is packed with iodoform gauze, or other antiseptic material, and this constitutes a quite important procedure. The packing should be thorough, the attempt being to keep the wound widely open, and everything is done to favour granulation from the bottom; otherwise it sometimes happens, as in the case before us, that there will be a hasty and superficial granulation, which, on account of weakness, one must tear open again, or else there may result some small sinus or cavity which, becoming filled with pus, will prevent the complete and solid occlusion of the wound for weeks.

This practically completes our operation. Careful antiseptic dressings are applied and firmly bandaged, and these should be left in situ for two or three days, when the wound may be redressed, and carefully irrigated; and it should be redressed every three days for several weeks. Note that no pad, truss, or other support is needed but is in fact contraindicated.

There are special points on which we can lay especial stress.

1st. The operation is almost devoid of all danger.

2nd. It is in fact a cure, no support or truss of any kind being needed, but rather to be avoided as tending to weaken the cicatrix and to thin the abdominal wall.

3rd. Even when suppuration and subsequent inflammation ensue, we still have nothing to fear; there is no closed cavity, and everything drains away to the point of least resistance, *i.e.*, to the surface in each case.

The question is often raised as on objection, "That the cord may be impringed and pressed on, and thus its functions interfered with and destroyed." Such, however, has not been the case. No trouble has arisen, in fact, and so far there has been no reason to doubt that the operation has accomplished all that is claimed for it; and just as we find that, often after years of labour resulting in some intricate and marvellous mechanism, a simple device finally fulfils the indications and requirement of the more complicated machine, so here our only wonder is, why the operation was ever done otherwise.

A brief summary from my notes may be of interest:

1.—J. B.; operation for inguinal hernia; single of right side; open method; highest temperature, 103.4° F. Temperature normal at end of first week. Suppuration slight, and due to catgut sutures; wound healed at end of four weeks. Patient walking at end of six weeks; cured at the end of tenth week.

2.—M. S.; operation; open method; double inguinal direct, of long standing and large size; highest temperature, 104° F.; temperature normal at end of second week, slight rise during the third week, again normal on careful irrigation: wounds about closed at the end of the sixth week; some slight suppuration due to rapid closure on right side. Patient up and about at end of the eighth week; under observation for three months; cured when last seen.

3.—E. M.; female; recent hernia; strangulated inguinal of left side; open operation; highest temperature, 103·1° F.; temperature normal at end of ninth day; wound healed at end of fourth week, patient working at end of the eighth week; cured.

4.—E. P.; inguinal; right side, of long standing; small in size; operation; highest temperature, 102·5° F.; entirely healed at end of three and one-half-weeks; patient walking at end of five and one-half weeks. In eight weeks cured.

5.—M. T.; re-operation by open method (after McEwens' operation had failed, being followed by local peritonitis, sloughing and suppuration of omentum); highest temperature, 103·5° F., middle of second week. At the end of fifth week wound nearly healed, with the exception of a long fistulous tract leading into the abdominal cavity some eight inches long. Patient did finally recover at end of three months; protracted healing being due to trouble in closing the afore-mentioned sinus. Final recovery perfect.

6.—M. C.; single, inguinal direct, of long standing; highest temperature, 102·8° F.; wound entirely healed at end of fifth week, and patient sitting up. Complete cure and recovery at end of seventh week.

7.—F. B.; single inguinal hernia, left side, of short duration; operation by open method; highest temperature on third day, 100·4° F.; on tenth day wound almost entirely granulated; patient's temperature normal on sixth day, patient still under treatment, now two and one-half weeks after operation.

REMARKS ON FEMORAL HERNIA.

To the eighth case, or rather the seventh in point of time, and the case presented to-night, I wish to call espccially attention. The problem in femoral hernia seems to be of less importance than the inguinal, and would appear to be less difficult to deal with. In the inguinal canal we have a permanent natural outlet to the abdominal cavity; while in the case of the crural canal we have an artificial production, no canal existing in reality, except by dissection or by the production of such a canal by pressure of the abdominal contents or changes produced by disease or pregnancy.

It has always seemed to me that the conditions existing in femoral hernia are so nearly analagous to those in the case of inguinal, that an operation applied to one could be easily reproduced in the other. So far as I can find, no one has yet made trial of the "Open Method of Operating on Femoral Hernia;" it was, therefore, with heightened interest that I have watched the case before us to-night, which I present to you as the first of its kind.

Let us *again* then, place before us clearly our problem. We have as before the abnormal condition of the peritoneal cavity, which, in each case, must be considered as the prime factor in keeping up hernial tendency, and we have an artificial canal a quarter to half an inch long, bound by strong fibrous tissues.

We have an artificial opening, the femoral ring, caused by the destruction of the septum crurale, and a second ring, if we please to continue the similarity at the saphenous opening, caused by the destruction of the cribriform fascia. We have also a number of borders and bands of strong fascia tending to restrain the hernia in the first place, and to prevent its return and produce strangulation in the second place. We have also to keep in mind the femoral vein and artery, in the same sheath in the canal to its outer side, the anterior crural nerve, and also the epigastric artery at the upper and outer portion of the femoral ring.

Thus are reproduced many points of similarity to the inguinal canal. If our operation succeeds we trust to restore the peritoneal cavity again to its normal condition, to close the femoral ring so far as the compartment produced by the hernia is concerned, and to close the canal with granulation tissue, as well as the saphenous opening; but a difficulty arises here analagous to the spermatic cord in the inguinal variety, *i.e.*, may we not injure by pressure or by inflammatory action, the integrity of the femoral vessels. This question can, of course, only be settled by time. In the case before us there has been considerable inflammatory action, but there seems to be no interference with the vessels in any way. In place of any theoretic remarks on this form of hernia, I shall simply relate to you the history of the case presented, and give a concise statement of the operation and some remarks on the result.

8. E. M., æt. 20, English, school girl. Family history: Mother nervous, father and two brothers have hernia, one brother consumptive. Patient has not been in good health for some years; menstruation irregular; bowels inactive. Seven years ago, while playing, the rupture on left side (femoral) occurred; this was reduced, but patient has never been able to wear a truss or to keep the hernia in position. Several times the hernia has been partially strangulated. For some months past the patient was unable to do work of any kind, and finally submitted to a Heaton's operation, but without result. On exami-

nation, a femoral hernia of left side about the size of an orange was found, giving impulse on coughing, and reduced without much difficulty. Also found same condition on right side, but very small, and limited to the crural canal. An operation was decided on. The patient was prepared as before described for the inguinal operation, ether administered, and, assisted by Drs. Cleland and Collins, I cut down upon the site of the hernia, keeping half-inch inside the course of the femoral vessels. A careful dissection brought into view the cribriform fascia and falciform process of the fascia lata, together with the bed of the hernia. The sack was carefully dealt with, according to the method described for herniæ of small size, and passing the finger through the saphenous opening and up the crural canal, entrance through the latter was easily had to the abdominal cavity; the tissues forming the roof of the canal were slit up to the internal opening; the femoral vessels in their sheath were exposed, and carefully held aside by an assistant; the internal or femoral ring could be plainly distinguished, and a strong suture of silkworm gut was passed from a point just inside the course of the femoral vessels and flush with the internal ring, diagonally upwards and inwards, and firmly tied. The internal ring was thus entirely occluded, as was demonstrated to the gentlemen present by personal examination. The tissues of the outer edge of the wound were then carefully drawn over the femoral vessels, and stretched to the bottom of the wound, thus forming an artificial canal; and the inner edge of the wound was treated in the same way; drainage was supplied by a decalcified bone tube, the wound packed with iodoform gauze, and the limb bandaged with a spica bandage of bichloride gauze—time of operation being thirty-eight minutes. The patient reacted nicely from the ether, but complained of much pain at seat of the wound; this pain soon disappeared. The temperature just after the operation was 98.5°; it reached a maximum height on the fourth day of 104.1°. The wound granulated nicely, in fact too rapidly, and I was obliged to keep it open by tearing away the fresh superficial granulations. Pneumonia of the right side developed during the fifth week, causing a rapid rise of temperature to 104°, and I prepared to open the wound, expecting to find pus enclosed, but upon examining the lungs I discovered the pneumonic process.

In spite of care the wound came together too rapidly, and left a small sinus which, though nearly healed at the present time, still exudes a few drops of pus. On account of pneumonia the patient was confined to bed until the ninth week, since which time she has been up and about, and was soon feeling better than before the operation. Two weeks ago the patient began doing housework, and has swept, carried coal, and cooked for a family of eight, together with the general care of a large house, with no return of the hernia, or symptoms of return. You have noticed the deep cicatrix binding firmly the site of the femoral canal far more securely than any truss or bandage could do. No truss or other appliance of any kind has been used, and now at eight weeks from the time of walking the condition of the wound seems better than ever, and more secure and firm. The case, however, speaks for itself, and if it continues to perform its functions as heretofore, we may confidently hope to call it a cure after it has stood the test for a sufficient time.

My object in citing this case is to call your attention to the possibility of broadening the field of the open operation to include femoral, as well as inguinal, herniæ. My, perhaps limited, research fails to find any record of a case of femoral hernia treated in a similar manner, and should it prove to be as sure and safe as the same operation for the inguinal variety, I feel sure you will agree with me that the operation is one of the leading surgical advances of the day, one well worthy of the close attention of us all, and reflecting great credit on Dr. Charles McBurney, who has, perhaps, more than any other surgeon, brought the operation to perfection and prominence.

His article in the *Medical Record* for March, 1889, is well worth reading, and I consider it the most masterly treatment of the subject yet devised. As I have before said, I have no desire to criticise other methods, for the results of each method have proven them to be limited to special cases, where cures were affected. Other cases have been called cures, while a truss or other support is as constantly worn.

Here, in this method, we have an operation devoid of risk, applicable to any case whatsoever, giving us an abdominal wall more secure than the normal, and not needing any support or appliance, but in which we rather court the supposed dangers of lack of support.

I trust that I shall not be misunderstood. I would not say that every hernia, inguinal and femoral, should be operated upon; I do not include in these terms infantile herniæ, which should be spoken of separately.

My idea here is rather to bring to your notice the operation; in another paper, at some future time, I trust I may have the pleasure of placing before you the reasons for the operation in a somewhat different way, and for causes other than those we at present speak of.

Finally, I trust you will not hastily condemn me as being rash or inconsiderate in striving to widen the scope of the operation to some extent, for I think the true physician or surgeon should be free from bias or prejudice, and untrammelled by any of the sad consequences of rashness.

Although, in my own mind, the operation extends much farther than the limits I have here set down, I would not even allow their expression until there is no doubt of their truth.

Thanking you for your kindness and attention, I will now leave the matter to your consideration.

The Spirit of the Societies.

The Clinical Society of Manchester, Tuesday, November 19th (Dr. Railton, president, in the chair). **A Case of Rickets with Unusual Deformity.**—Dr. Railton showed a girl, æt. seven and a half years, who, in addition to many of the customary deformities, had a remarkable bilateral flattening of the upper two-thirds of the shaft of each humerus. The anterior bicipital ridge projecting almost like a knife-edge beneath the skin. The affected portions were also curved, with the convexity forwards from above downwards, the posterior aspects being correspondingly concave. The symptoms of rickets had apparently not shown themselves until after the end of first dentition. Dr. Railton suggested the possibility of the flattening and bending being caused by the anus having been grasped at that part while the bones were in a softened state.

Radical Cure of Hernia.—Mr. E. Stanmore Bishop read a paper on the above. After some remarks as to trusses, and the objections to their continuous use, he gave a short sketch of the various operations at present available, and described a modification of the latest, that of Dr. Macewen, which he had used and found satisfactory. It consisted essentially of a novel manipulation of the sac, and was based upon Macewen's principle of reduction of the sac into the interior of the abdomen.

* * * *

Royal Academy of Medicine in Ireland (Dr. E. H. Bennett, president).—The President delivered an introductory address.

Fracture of the Skull, with Hernia Cerebri.—Dr. T. Evelyn Little brought forward a case of fracture of the skull, with hernia cerebri, in a child. The patient died on the fourteenth day in an attack of convulsions, there having been no symptom whatsoever pointing towards a fatal result until a few hours before death. At the *post-mortem* examination meningitis was found over both hemispheres, and an excavation in the frontal lobe corresponding to the seat of the injury.

The President said the disproportion between the injury to the bone and the injury to the brain was fully borne out by the experiments, which had demonstrated the great elasticity of the skull in children.

Dr. Swanzy said the feature of the case which had interested him most was the symptom of the turning of the head towards the side on which the injury was situated. As Dr. Little had mentioned, that was generally associated with rotation of the eyes in the same direction. There was a conjugate deviation of the eyes and head towards the same side. But they might have one part of this duplex symptom without the other. In health a very discursive motion of the eyes to one side was usually associated with a motion of the head in the same direction; nevertheless, by a slight effort of the will it was possible to turn the eyes while the head was kept steady, or to turn the head while the eyes were fixed. Consequently they need not be surprised if in any diseased condition they should occasionally find one part of this duplex symptom without the other. With regard to the position of this centre of motion of the head and eyes, Ferrier, by experiments made some years ago on monkeys, satisfied himself that it was situated in the superior and posterior parts of the middle frontal convolutions. Some time afterwards Grasset argued from clinical observations that the site was in the inferior parietal lobuli. Some time after the site was placed by Horsley again in the frontal lobe. A few months ago Wernicke ascertained to his complete satisfaction that it was situated in the inferior parietal lobuli; and now they had Dr. Little placing it in the frontal lobe.

Dr. Little, in reply, admitted that there were different theories with respect to conjugate deviation of the head and eyes. As to the deviation in this case having been due to some more distant lesion of the brain, he felt some difficulty in adopting that supposition.

Although the amount of brain substance lost was very considerable compared with the injury, still it was remarkably definite and remarkably local; and these circumstances were of importance in connection with the question of localisation. To say that the lesion here might have produced symptoms of interference with centres in other parts of the brain was no more than what could be said with respect to any lesion, traumatic or from disease, in any part of the brain.

Case of Renal Calculus.—Dr. J. K. Barton communicated a case of renal calculus, which had been successfully removed by a surgical operation. The calculus had been tightly wedged into the calices of the kidney.

Dr. Foot asked was there any history of hæmaturia in the case? The symptom was an obvious one in the diagnosis of renal calculus; still he should not have thought it likely to occur here on account of this being a fixed calculus.

Dr. Barton, in reply, said the patient had no hæmaturia. The urine was faintly acid, but became alkaline after it had stood for some time.

Case of Conjunctival Cyst.—Dr. J. B. Story submitted a conjunctival cyst which had been removed from the eye of a baby aged six weeks. It was attached to the cornea, and sent a band backwards to the internal rectus muscle, from which it had to be raised by a strabismus hook. The cyst was a dermoid, and Mr. Scott exhibited microscopic sections of its wall. Mr. Story commented upon the presence of these dermoid cysts in cases of coloboma of the lids, and dermoid bands uniting the globe to the skin of the face, and stated his approval of the theory of Van Duyse, who attributed all these defects to the existence of amniotic adhesions in embryonic life.

The President remarked that adhesions between the amnion and the surfaces of the embryo were the greatest cause of these congenital defects.

Tubercular Kidney.—Dr. Heuston submitted an example of tubercular kidney in a boy, æt. thirteen, which had been successfully removed by surgical operation, and said there were microscopic specimens of the kidney on the table showing the giant cells and other evidences of tubercular disease. He has been unable, however, to detect in these specimens the bacillus tuberculosis.

* * * *

Liverpool Medical Institution (Dr. Carter, president). **Excision of Right Shoulder.**—Dr. Damer Harrison showed a patient after excision of shoulder, including a large portion of scapula.

Stricture of the Urethra, Extravasation of Urine, etc.—Dr. Rushton Parker read a paper on the above subject, in which he described the operation of internal urethrotomy with Maisonneuve's instrument as generally practised by himself in narrow strictures. He had performed ninety operations, other than the passage of bougies, and had had five deaths (there being cases of external urethrotomy, of which two were for extravasation and gangrene out of the ninety). There were sixty-three cases of internal urethrotomy, of which one died apparently from the operation, a second was moribund at the time of operation, and a third was unrelieved, but had extravasation and gangrene, for which perineal section was subsequently done without saving the patient. Mr. Parker spoke highly of Lister's polished metallic bougies of conical shape, with olivary tips, as facilitating continuous dilatation, which under chloroform can be rapidly effected even in rigid strictures. Under any circumstances he preferred, after any severe instrumentation, to leave an easy exit for urine from the bladder. In extravasation he advocated median incision of the perineum in the first instance without incising the scrotum. Should the case be attended with gangrene, counter openings can then be made, but if not the scrotum can be spared. He had twice met with extravasation of sweet urine for which single perineal incision sufficed.

Mr. Puzey said he had never practised internal division except in cases of penile stricture. The practice of "vital dilatation" in the old-fashioned way as taught in his student days at Guy's, was still good enough for him, and he saw no reason to try a more questionable operation. He believed that it was not only safer, but more permanent in its good results. When a cutting operation was required, he preferred external urethrotomy, as being not only a safer operation, but as allowing more precision and completeness in dividing the stricture. He had never had the slightest difficulty or complication arising from the operation itself, although this, as another treatment, would fail to produce a successful result when the kidneys were hopelessly diseased. With regard to cases of extravasation of urine due to stricture, a free incision in the median line (generally followed by drainage of the bladder) was in most instances the main feature of surgical treatment.

New York Surgical Society, October 9th, 1889 (Dr. Lewis A. Stimson, president). **Intestinal Strangulation.**—Dr. L. S. Pilcher, of Brooklyn, presented a specimen taken from a case in which the patient had died after a laparotomy for the relief of intestinal strangulation, with the following history: A man, æt. thirty-seven, was admitted into the Methodist Hospital on September 14th, with symptoms of intestinal obstruction. The abdomen was tympanitic, rigid, and tender; pulse, 140; temperature, 100.4° F. He was vomiting frequently a greenish fluid, without feculent odour; his attending physician stated positively that on the preceding day he had vomited feculent matter. Ten days previously he had had his last normal stool; four days before admission he had had a slight movement of the bowels, described as black and tarry in character. Seven days before admission he had a transitory attack of severe colicky pain in the abdomen; previous to this time he had supposed himself well, as he always had been. This attack did not prevent him from working as usual for the next three days, after which time the colic returned, accompanied with vomiting, and these symptoms persisted until his admission into the hospital. Cathartics, opiates, and enemata had been used vigorously before his admission. After his admission another enema was administered, without result. The stomach was then washed out, after which laparotomy was proceeded with. Exposure of the intestines revealed a general peritonitis already present, with great distension of the small intestine throughout its whole extent. The incision was lengthened sufficiently to permit of the ready turning out of the small intestine; the large intestine, quite empty, was then traced backward, beginning on the left side; at the hepatic flexure it was found to be imbedded in a mass of old organised inflammatory material, which bound it to the posterior wall of the cavity. This formed a band an inch or more in breadth, glueing all the adjacent structures together; on the proximal side of the band there was the livid, softened, distended ascending colon. It was evident that any attempt at breaking up the inflammatory adhesions would be attended with great risk of rupture of the intestine, a risk that was increased by the depth of the involved parts from the surface. The speaker accordingly proceeded at once to circumvent the obstruction by forming an anastomosis by bringing the lower portion of the ileum up to the ascending colon a few inches beyond the point of obstruction. This was accomplished by the use of Dr. Abbe's catgut rings. Great difficulty was experienced in returning the distended small intestines, and a puncture was necessary to empty them. This being closed, they were returned into the abdominal cavity. The patient never rallied from the shock, but died within an hour after his return to bed. The autopsy showed a chronic ulcer of the ascending colon, which had not perforated the peritonæum, but had, nevertheless, occasioned the local peritoneal exudation that had caused the obstruction. It was found that, so far as the anastomosis was concerned, everything had been accomplished that had been attempted at the operative procedure.

Dr. Abbe thought that in these cases of acute obstruction the operation for effecting anastomosis had better be delayed until after the colostomy. The shock was too much for the patient to stand. After obtaining relief from the colostomy there was no danger after a fortnight in anastomosis.

Dr. Abbe presented a specimen illustrating a typical case of internal intestinal strangulation by a band. A lady of thirty-five was suddenly seized with vomiting and hypogastric pain. She was attended by a physician who endeavoured to bring about purgation. Enemata, calomel, and other purgatives failed. Not even wind passed the bowel. Vomiting increased, and on the third day became stercoraceous. The abdomen became tympanitic, but showed no dull area to suggest the seat of obstruction. At the end of the fourth day, when she was first seen by Dr. Abbe, she had already for six hours shown characteristic apathy and exhaustion. Her temperature was normal, her pulse 100. Laparotomy was immediately resorted to under ether. The abdomen was found filled with distended and highly congested small intestines, among which was seen a small coil of pale and empty intestine. This and the distended gut both terminated in Douglas's *cul-de-sac*.

The Fallopian tube on each side was turned upward and fixed by adhesion so as to form a tight pocket behind the uterus, in which was caught a strangulated knuckle of the ileum, with its adjacent coil for three inches. The attempt to move it was futile, on account of fixation, and, as the patient's strength began to flag, he was obliged to do an ileostomy of the lowest distended coil as rapidly as possible. The patient lived five hours and died of the shock of strangulation plus operation.

The gut was found gangrenous under the line of the strangulating band. Fæcal vomiting occurred twice after the operation.

Pathological Society of London (W. H. Dickinson, president).—The President opened the session by referring to the migration of the society from Berners-street to Hanover-square. He said the council had agreed to pay the Royal Medical and Chirurgical Society one hundred guineas instead of seventy-five, as the accommodation now offered them was much larger.

Addison's Disease in a Diabetic Patient.—Dr. Samuel West read the notes of a case of diabetes mellitus which occurred in a patient, æt. forty, affected with Addison's disease. The urine contained 2.5 per cent. of sugar, had a specific gravity of 1034, and contained a trace of albumen. The liver was enlarged and tender, and there was a little dulness at the base of each lung. The skin was discoloured, and of a greyish colour. After admission to hospital the patient had dysuria, which was due to cystitis, and caused a temporary rise in the temperature. Careful diet with pilocarpine, and a small quantity of opium was prescribed, and there was a considerable diminution in the quantity of sugar in the urine. A month after admission an attack of subacute rheumatism developed; temperature rose to 105°; vomiting set in, and the patient died. The suprarenal capsules were found at the necropsy to be embedded in dense fibrous tissue, by which they were bound to the kidney on each side, and to other parts in the neighbourhood. Dr. West regarded the association of diabetes with Addison's disease, as nothing more than an accidental coincidence.—Dr. Wilks referred to the remarkable fact of Addison's disease being found in association with diabetes.

Hypertrophic Cirrhosis in a Child.—Dr. F. G. Smith read the notes of the above from a specimen sent to him by Mr. J. A. Jones, of Aberavon, in a little girl æt. four and a half years. Their was no hereditary taint of any form. The child suffered from icterus neonatorum at birth, but this cleared up entirely in a few weeks. At the age of three and a half she had rackets and jaundice, but both conditions cleared up under treatment, though the liver ever after was felt to be enlarged. At four years she had another attack, from which she never rallied; she died in six months.

Congenital Heart Disease.—Dr. Norman Moore showed and described the following specimens: The heart of a girl eight and a half years, who was a patient of his at St. Bartholomew's Hospital, and died of abscess in the posterior half of the left lenticular nucleus, with basal meningitis. The upper part of the septum centricularum was absent. The pulmonary artery was very small, and opened from the right ventricle somewhat nearer the middle line than natural. The origin was surrounded by a thickened base, and no valves were visible unless this base was formed by thickened and adherent valves. The arch of the aorta was dilated, and so was the right auricle. The ductus arteriosus was closed, but a deep pit marked its insertion into the aorta. The left common carotid and innominati were nearer to one another than was commonly the case. The patient had been blueish and short of breath from birth. Her fingers were clubbed. A loud cystolic murmur was audible over the whole cardiac area, and also at the angle of the left scapula the loudest, and at the second left intercostal space near the sternum. The cerebral abscess was probably due to an embolon from a firm anti-mortem clot contained in the right auricle, and which came very near to the orifice of the aorta.—Dr. Stephen Mackenzie mentioned the case of a man who had been admitted into the London Hospital for syphilis in an early stage, with the chancre still recent, and a secondary eruption out upon him. Soon after his admission he had died suddenly, and at the *post-mortem* examination a gumma was found in the heart, which had undoubtedly caused his death. This case had often been referred to on account of the early stage of the disease in which a gumma was present.

* * * *

Midland Medical Society (William Ross Jordan, president.) **Amputation of Leg.**—Mr. Jordan Lloyd showed a leg that he had recently amputated for chronic ulceration. There was great hypertrophy of the skin, and subcutaneous tissues, together with some thickening of bone.

Malignant Disease of Rectum.—Mr. Marsh read a paper on the treatment of malignant disease of the rectum, and showed a patient from whom he had excised the rectum after having done a preliminary colotomy.

Muscular Atrophy in Locomotor Ataxy.—Dr. Suckling showed a stenographer, æt. twenty-nine, suffering from locomotor ataxy, with well-marked muscular atrophy. The man had lived in America for four years, and had suffered from ague. His present illness began in December, 1887, when he was seized with incessant vomiting. After a year these attacks became frequent, and now occurred every few days. In June, 1888, he noticed his hands were numb, the numbness beginning between the index and middle fingers, and since that time his hands, feet, and forearms had wasted; legs also. He had since lost the use of his left arm. His hair was grey, and he was emaciated and feeble. The man had never had syphilis, and had been steady, and there was no hereditary history. Suspension was tried in this case, but could not be borne. Quinine was useless. Morphine was the only thing that gave relief.

The officers and council were elected. *President:* Lawson Tait. *Members of Council:* Dr. Holmes Joy, Dr. A. Underhill, Dr. Simon, Mr. Bennett May, Mr. Jordan Lloyd, Mr. Messiter, Mr. Chevasse, Mr. Bailing, Mr. Priestly Smith, Mr. A. Clay, Mr. Eales, Mr. W. Thomas. *Treasurer:* Mr. Garner. *Secretaries:* Dr. Suckling, Mr. Haslam.

* * * *

Bradford Medico-Chirurgical Society (T. C. Denby, M.D., president). **Disseminated Sclerosis.**—The President showed a case of disseminated sclerosis, complicated by the presence of exalted ideas, which at first made the diagnosis from general paralysis difficult.—Dr. Major also made some remarks on the case.

Disease of Cerebellum.—Dr. Major showed a specimen of the above disease, in which the diagnosis, *inter vitam*, had been made of a tumour of the middle lobe pressing on the motor tracts of the medulla, and causing paralysis. A peculiar feature was almost constant lividity of both arms. The *post-mortem* examination showed a large cyst occupying the middle lobe and part of the left hemisphere, filled with clear water.—Drs. Goyder, G. Carter, and Mr. Althorp joined in the discussion, the latter advancing a suggestion that this cyst might be a fœtal remainder of a ventricle in the cerebellum, as was to be found in some birds.—The President also recorded a case in which the cerebellum had been filled with small tumours.

Prolapsed Ovary.—Dr. Goyder read notes of a case of prolapsed ovary, in which he had successfully reduced the ovary, and kept it in position with a modified Hodge's pessary.

Empyema of the Maxillary Antrim.—Dr. H. Bronner read notes of a case of empyema of the maxillary antrim successfully treated by drainage.

* * * *

Leeds and West Riding Medico-Chirurgical Society (A. F. McGill, president). **Chloride of Zinc as a Caustic in Cancer of Female Generative Organs.**—Dr. Braithwaite read a communication on cases illustrating the advantages derived from the use of chloride of zinc as a caustic in cancer of the female generative organs. In the course of his remarks he saw (1) that the knife should be first used, when possible, and in case of its return the zinc should be applied. (2) There were some cases where the zinc could be used first, and, indeed, the only weapon, as in commencing cancer of the cervical canal of the uterus, when from any cause the organ could not be pulled down into view, as when the uterus was fixed by old inflammatory adhesions. In commencing cancer of the vulva or vagina, if the disease were superficial and not of great extent, this treatment alone was necessary. (3) It should be applied by means of a thin layer of cotton wool, wetted with the zinc solution, and lightly pressed between two pieces of blotting paper. It then did not run. (4) A saturated solution should be used. (5) The caustic required time: twenty-four hours was generally the time it took to act, but if a deeper action were required, it might be left longer. (6) It was followed by a great contraction of the parts, which was to some extent a safeguard against its return. He (Dr. Braithwaite) thought it superior to Paquelin's cautery, acid nitrate of mercury, and potassa fusa.—Mr. Mayo Robson did not agree with Dr. Braithwaite, not being convinced of the utility of the procedure advocated by him. In the first two cases cited, only a few weeks had elapsed since they had been treated, and already other applications had been required. The third case had resulted in sloughing of the cervix when the disease had not been proved cancer; and in the fourth case, merely temporary relief had been given. Mr. Robson thought that when cancer of the uterus could be removed by the scissors and knife, it should be done; but when the uterus was fixed, and the disease was beyond the reach of the knife, the application of caustic was dangerous, uncertain, and unscientific.—Mr. Croft thought Dr. Braithwaite had somewhat over-stated his case as regards the question of pain. At any rate, in those cases with which he was associated, where the disease affected the vagina, the pain was severe, morphia being required two or three days afterwards.—Dr. Braithwaite, in reply, said that in many cases the pain was slight. As regards the reproach that his treatment was unscientific, he was of opinion that patients would prefer to be cured by methods that were unscientific, rather than be left to die, because the only available means of cure rested under that terrible stigma,

Harveian Society of London (Thomas Buzzard, M.D., president).—**Anti-Fermentative Treatment of Diarrhœa.**—Dr. Tuff read a paper on the causation and treatment of that variety of acute infantile diarrhœa produced by irritative products resulting from fermentations set up in milk, either previous to or during ingestion. While admitting that though probably several irritating substances resulting from the fermentation of milk were factors in the production of the form of acute infantile diarrhœa under consideration, he contended that the principal share of the blame rested with the milk or cheese ptomaine, tyrotoxicon, produced during the fermentation of milk under certain conditions. Dr. Tuff referred to Dr. Illingworth's antiseptic treatment of infantile diarrhœa, which he had himself found most useful, and the employment of which had first directed his attention to the treatment he had used. This consisted in drug and diet combined. The drug treatment consisted in the administration of one-fiftieth of a grain doses of biniodide of mercury dissolved in iodide of potassium, combined with one-grain doses of chloral hydrate. It was shown experimentally that the soluble biniodide of mercury was an extremely soluble and diffusible salt, and that it possessed the property of combining with and rendering insoluble the milk ptomaine tyrotoxicon. Of eighty cases of diarrhœa treated by this method, the diarrhœa ceased within two days in seventy-two of the cases. In five out of the remaining eight cases, it ceased within eight days, and in no case did it last over seven days.

Surgical Aids and Appliances.

127.—THE NEW ANTISEPTIC ARTIFICIAL DRUM.

Dr. Ward Cousins writes:—"The new membrane which I desire to submit to the criticism of my professional brethren is represented in fig. 1. In shape, it is exactly like a hat with a very high and tapering crown, and a broad and flat brim, having a short ribbon attached to the edge. It is just firm enough in substance to retain its shape in the ear, and yet the material is so soft and flexible that it causes no sensation by its presence. It is

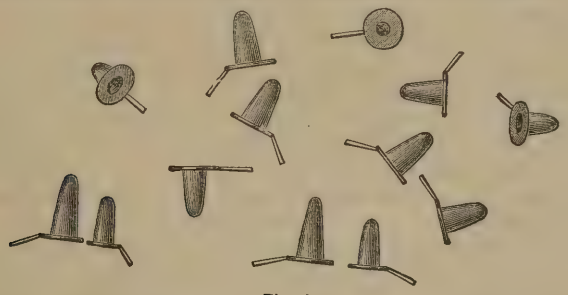

Fig. 1.

stained a delicate flesh-colour, and is made in several sizes to suit the varying capacity of the external meatus. When in position, the crown rests near the tympanic membrane, the brim upon the meatal wall, and the little ribbon or handle behind the tragus. The method of manufacture has been worked out by a series of experiments. The material is composed of compressed cotton fibre swollen by prolonged immersion, and saturated in an antiseptic oil and ether; the soft material is then firmly pressed in a little machine that I have designed for the purpose, and afterwards dried by artificial heat.

One marked feature of the new antiseptic membrane is its extreme lightness. The weight varies a little, according to the size, and this has a range of one-sixth to one-quarter of a grain. I have often introduced it without the patient being aware that anything had been put into the meatus. Another special quality consists in the facility with which it can be introduced and removed by the patient himself. The little instrument for the self-application of the artificial membrane is depicted in fig. 2. The probe end is inserted into the crown of my little hat, and in this way it can be accurately placed in the meatus, and then detached from the instrument by the aid of the sliding collar. Patients very soon get into the way of adjusting it and slipping it into position with just the right amount of pressure for securing the best result. The forceps is intended to be used for the removal of the artificial membrane, and in doing this patients are guided by their tactile sensibility. Traction is made upon the handle, which ought always to be easily found resting just behind the tragus. It is a matter of great practical importance in every case that the artificial membrane should be selected to suit the shape and capacity of the external ear. It is my practice to regulate the height of the crown by the sensations of the patient, and the breadth of the brim by the size of the meatus. It must not fit too tightly, but simply rest in contact with the meatal wall, so that after it has been put into the right position, it does not get easily displaced.

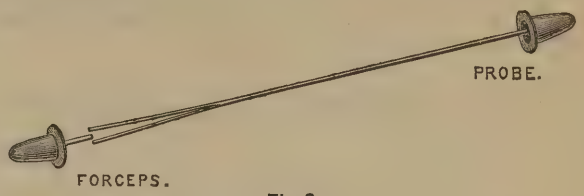

Fig 2.

Fig. 3 presents a diagrammatic section of the ear, showing the usual position of my artificial drumhead. It is not necessary to place the crown upon the perforation, or in contact with the remnants of the tympanic membrane. The surgeon cannot select the point of contact by any internal scrutiny of the organ, but in every case he must be guided by the sensations of the patient and the improvement produced in the hearing power.

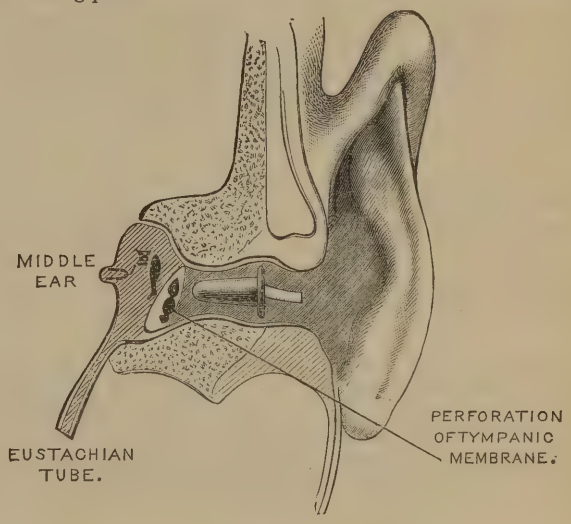

Fig. 3.

The artificial drumhead may be regarded also as an ear protector, and a local antiseptic remedy. I have recently made some impregnated with the oils of eucalyptus globulus, and pumiline pine in combination with other aromatic substances, and their agreeable fragrancy renders them extremely grateful to some patients, especially those who have suffered from offensive discharge. Other patients with perforation of the tympanic membrane, but without serious deafness, have used them as ear protectors with great comfort. In such cases the artificial membrane forms a screen between the middle ear and the external meatus and acts as an efficient shield during rough and cold weather."

Medical Miscellanea.

The subject of our next illustration will be Sir John T. Banks (Dublin).

* * * *

The Lord Mayor has sent 40,000 francs to the Pasteur Institute.

* * * *

Dr. Bantock has been elected an honorary Fellow of the American Association of Obstetricians and Gynæcologists.

* * * *

Dr. Donald Macalister has been elected representative of the University of Cambridge, on the General Medical Council.

Dr. R. W. Reed has been appointed Professor of Anatomy in the University of Aberdeen, *vice* Professor Struthers.

* * * *

Drs. Stephenson, Thorne, Corfield, and Ballard have been re-elected Examiners of the Royal College of Physicians for the diploma of Public Health.

* * * *

Dr. Oliver, house surgeon to the Preston Infirmary, gave proof of his devotion to medicine and to the interests of his patients by affording the blood required for transfusion into a patient.

* * * *

Owing to the increasing popularity of *The Nursing Record*, an American edition is published every week by Messrs. Bromfield & Co., 658, Broadway, New York.

* * * *

Dr. W. A. Smyly has been elected Master of the Rotunda Hospital, Dublin, *vice* Dr. Macan, for seven years. What possibilities are open to him!

* * * *

Sir Edward Guinness has given a quarter of a million to be held in trust for dwellings of the labouring class. We trust that this money will be expended for the benefit of the people the beneficent donor had in view.

* * * *

The following medical men have been elected mayors for the ensuing year:—J. S. Bartrum (Bath), second time; Mr. William Kirk (Hedon); D. H. V. Paulin (Wrexham); D. Sherburn (Hull); Alderman James Coomlis, M.D. (Bedford), second time; Alderman Hugh Moss, M.D. (Congleton), re-elected; Mr. H. Lankester (Leicester); J. M. Morison (Pembroke); Mr. J. Woodhard (Rye).

* * * *

Dr. P. Murray Braidwood has received an award at the Glasgow Exhibition, for his exhibit of plans of hospital ships. This memorial diploma is a beautiful work of art, and along with similar awards for the same subject, obtained at the Liverpool, and Adelaide South Australia Exhibitions, is a gratifying testimony to the usefulness of Dr. Braidwood's idea, and its adaptation to the intended purpose of relieving the sufferings of the sick and wounded at sea.

* * * *

The Duke of Westminister has just thrown open to the public a new garden in Duke-street, Grosvenor-square, a little more than one-third of an acre in extent, laid out by him on part of his estate from which old worn-out tenements have been removed. Sir Sydney Waterlow has also given for the use of the public of the metropolis, a freehold estate of twenty-nine acres on the southern slope of Highgate-hill, well timbered, and containing one acre and a half of ornamental water.

* * * *

The Bishop of Ely, the Bishop of Bedford, the Archdeacon of Oxford, the Vicar of Brighton, and the Medical Officer of Health for Wakefield, have recently presided at Conferences held under the auspices of the Church of England Burial Reform Association, at Cambridge, Westminster, Oxford, Brighton, and Wakefield respectively. Among those who took part in these meetings were Sir Spencer Wells, Bt., Gen. Lowry, Canon Ince, Canon Bright, Canon Heartley, Canon Freeling, the Warden of Keble, Dr. Septimus Gibbon, and Professor Hodgetts. At each conference it was unanimously resolved to memorialise the Government for the protection of the public against the dangers involved in the continued general use of over-crowded cemeteries, and for the amendment of the Burial Acts.

* * * *

It is intended to erect a monument in memory of the late Dr. Prescott Joule, of Manchester. The *Journal of the American Medical Association* has the following discriminatory notice of this distinguished English *savant*:

"Dr. James Prescott Joule, who died at Sale on October 9, in the 71st year of his age, was one of the most distinguished men of science which this country has ever produced, and is entitled to be reckoned one of the greatest of original workers in pure science. His great achievement was his determination of the mechanical equivalent of heat. The consequences flowing from the working out of this problem, which was achieved by Dr. Joule with the most consummate skill and admirable completeness, are to be noted in almost every department of science; upon his demonstrations the whole theory of the correlation of forces is mainly based. The most important practical applications have been in the mechanical arts, but even physiology is his debtor."

Correspondence, Notes, and Queries.

Communications, Books, etc., should be addressed directly to the Editor, "*The Provincial Medical Journal*," *Horton House, Halifax.*

Matters of business should be addressed to the Publisher, at the Offices, 10, *Friar Lane, Leicester.*

MSS. intended for publication to be sent in not later than the 16*th of the month.*

The insertion of any letter in these columns cannot be taken as necessarily indicating our adhesion to the views or statements therein expressed. The same remark applies to articles to which a name or nom-de-plume is attached.

HOSPITAL OUT-PATIENT REFORM AND THE PUBLIC MEDICAL SERVICE.

To the Editor of The Provincial Medical Journal.

Sir,—The following figures, given in tabular form, will help to show how very many persons in this country are receiving free medical relief in one year:

Number treated at 759 hospitals and dispensaries	2,828,296
,, ,, 118 ,, ,, ...	(no returns)
Number receiving Poor-law medical relief, medicine included ...	831,353
Number treated in metropolitan fever hospitals	6,537
Number treated in provincial cities and towns fever hospitals ...	(no returns)
Number receiving free private medical aid from doctors	338,600
Total receiving free medical relief	4,004,786

As regards the number treated at the voluntary medical charities, it has been said that one patient is counted two or three times over. I should like some proof of this. The Poor-law numbers are collected twice yearly only—in July and January—so that all the Local Government Board report says is, that on these two dates so many persons are in receipt of relief. If all were counted in who come between these dates the number would be much larger. If we had the total number of fever cases treated in the various municipal fever hospitals, the total would be very much greater.

As to the number receiving private aid from doctors, I take it that each doctor treats twenty such cases yearly. If we refer to the fourth report of the Statistical Committee of the Medical Council of 1888, we find that there were 16,930 doctors practising in England. This multiplied by twenty will give the above number. The population of England being 28,000,000, this gives us the deplorable fact that one in every six says he or she is unable to pay for medical advice. The above numbers do not include the 457,301 persons who received free vaccination in one year. Nor do they include those treated at the various charitable homes for widows, orphans, fallen women, and such like. I think if one said that one in three was provided with free medical relief in this country, a very near approach to accuracy would be made. I do not say that the medical profession is not paid something for treating some of the above; but I have no hesitation in stating that if all the money received were evenly divided over the above number it would not exceed 2d. per annum per patient.

One correspondent has said that our profession should be a religious calling and not a business. Very well. But are we not told that true charity should begin at home; and that, instead of depending on these

benevolent institutions, we should make due provision for ourselves, our wives, widows, and children? There is no reason, moreover, why a religious profession should be an unpaid one. Is the labour not worthy of his hire? Each clergyman in the Scotch Church has £200 a year at least guaranteed him. In the Church of England each curate has about £120 a year. What doctor has such advantages as these: But the chief point to grasp that we doctors, in giving free treatment to hospital patients, are not performing a charitable act, as it is well known that many thus supplied are in sense deserving of our charity. True charity consists in giving to the proper kind of applicants, and not in making and encouraging well-to-do paupers. True charity also consists in not only relieving disease but in removing the causes which produce it. Why do our hospital reports say each year they are glad to say that there is an increase in the number of patients? Is this anything to boast of? If disease is preventible, we shoud be ashamed of the fact.

The above figures have for so far been unchallenged, and may, I feel, be taken as fairly accurate. This being so, surely it rests with the medical profession to recognise its great responsibility, and to come forward with a scheme by which good honest treatment may be provided for the working classes. The very fact that cheap or sixpenny dispensaries flourish proves the necessity for our providing. If anyone will refer to the *Journal* of August 10th he will find a tabular statement of the average weekly wages paid to sixty-nine trades union workmen, taken from Blue Book C. 5,505, this showing clearly, I think, that these classes are well able to pay small fees, and only such. This is further proved by the fact that the last census returns showed that there were 8,649,259 of industrial classes between the ages of fifteen and sixty-five in England of a population of 36,000,000; over 30,000,000 of these are in receipt of salaries of less than £150 per annum. Yet how can these pay 3s. 6d. or 5s. fees? The vast amount of sickness, again, proves the necessity for our action. Sir James Paget has shown that 15,317,204 men and women between fifteen and sixty-five suffer over 20,000,000 week's sickness, and if we calculate that each one of the entire population suffers on an average nine days' sickness, this will give us a total sick-rate for the entire community of 38,845,000 weeks. At least 13,248,950 persons are ill each year in this country. It will not do to say that the various friendly societies supply the want of medical service, for of the 4,000,000 members belonging to these, about 2,000,000 are insured for sick pay and a doctor; the others belonging to burial societies. It is, therefore, to be hoped that doctors will now try to bring about a lasting reform in our hospitals. If we all tried for once to agree, and not boast that each one had a special solution of the difficulties, then there would be very little call for any Government inquiry, which must show, I fear, that the medical profession has been doing its best to pauperise a very large portion of the well-to-do public. What ends we have to gain in doing so we must know best. At all events the subscribing public are looking rather askance at the present state of mismanagement. Whose fault is this?—I am, etc.,

ROBERT R. RENTOUL.

Liverpool.

A PUBLIC MEDICAL SERVICE.

To the Editor of The Provincial Medical Journal.

Sir,—Always desirous, as you are, to aid the interests of the profession, especially those of the general practitioner, I desire to ask you to call the attention of your readers to the circular issued in the *British Medical Journal* of November 9th, where the editor, by a few thoughtfully conceived questions, endeavours to get the views of the profession as to the utility of a Public Medical Service, as suggested by Dr. Rentoul at the late annual meeting held in Leeds. I trust everyone will at least manifest his interest by replying to these questions in this attempt of Dr. Rentoul to do something to relieve, if not to remove, the ever-increasing injury done to a large body of medical men, both by the great abuse of the out-patient departments of our hospitals and the numerous advertising sick clubs and private dispensaries, for unless something is done to relieve this clamour for publicity by a section of the profession, and the desire for almost gratuitous advice by too many of the public, the inevitable will be that the health of the community will suffer, and medical knowledge and skill will deteriorate, and the medical profession will cease to be the career of a gentleman.

We may not all, nor even the large majority, quite accept Dr. Rentoul's scheme. Indeed, many may think as I do, that the fees he suggests for certain operations too small, and that such fees will not enhance the appreciation of our art or the gratitude of our patients. But Dr. Rentoul deserves the thanks of the profession, and all must appreciate his efforts, the time he has expended, and the trouble and pains he has taken, to remove or to lessen the present difficulties the general practitioner experiences in his desire to attend the sick poor, who are able, and in most cases are willing, to provide for their own medical attendance and medicine when ill. We recognise the fact that this large class of poor, but who are not paupers, must have medical advice, including medicines, for fees very much smaller than the usual fees of a skilful doctor.

I do think the Manchester plan, if well carried out, would greatly limit the number now attending our hospitals as out-patients, and this Dr. Rentoul proves in his letter in this week's *Lancet*. The first year of the experiment, in 1875, "42.32 per cent. were found ineligible for gratuitous medical relief, and were in consequence referred to the branch provident dispensaries, and the preventive nature of the test is so well shown that the next year only 24.50 were found ineligible, and in 1885 only 13.57 per cent."

The abuse, too, of the club system, where no wage limit exists, is perhaps even "a greater injury and loss to the profession, and this is, I am told, especially the case in the country, where not only small tradesmen and artisans, but farmers and others earning even good incomes, join and expect free medical attendance and medicine for 1*d.* per week, and all certificates and examinations as to state of health without any fee. The rule of labour is thus glaringly violated, which in their own case the labouring class very quickly perceive, 'That unless remuneration bears a proper relation to the duties performed there can be no confidence or satisfaction between employer or employed.'"

What we require is to recognise some well-considered sliding scale of payment that could be considerately devised, and by the provident system as easily paid by even most poor people. Dr. J. S. Belcher's proposition, at p. 1129 in the *British Medical Journal* of this week, appears to me a good suggestion. Threepence per month is surely not too much if medicines are included (and this is necessary), even for a man who only earns 15*s.* per week, and should, I think, be the minimum monthly charge for one person. Neither is the addition he proposes of ½*d.* per week for each 5*s.* earned above the 15*s.* an excessive addition.

I hope this effort to get at the opinions and wishes of the profession upon this vexed question of providing medical aid to the poorer classes without impoverishing the profession may result in permanent benefit to many of us who are, and have been, very severely hit, both by the abuse of the hospitals and the numerous sick clubs that have sprung up, like mushrooms, in almost every neighbourhood, and may also lessen the lamentable results of the present unseemly competition between not a few of our medical brothers. If the Council, or a committee approved by the British Medical Association, would suggest some reasonable and adequate scale of fees for visits—fees for operations for poor patients can hardly be fixed; they must depend upon the liberality and time at the disposal of the surgeon, and serious operations are certainly for the poor best treated at the hospital—but for ordinary visits a minimum fee might be fixed—for instance, all who could not pay 2*s.* 6*d.* for a visit, or 2*s.* for a consultation, including medicine, should be attended by the proposed Public Medical Service, whose funds should be augmented by Government, or by public local subscription. Every registered medical man who desired should have the privilege of joining this medical service if he wished, and had been in practice two or three years with good repute. The poor would thus have a large body of responsible medical practitioners from whom to select their doctor, and not as now, at the mercy of the neophyte or charlatan, or even of the unprincipled medical man who is not ashamed to farm a number of cheap dispensaries, managed by unqualified assistants. I quite think some such plan feasible, and before we close or limit the attendances at the hospitals we must have some alternative by which the sick poor can have medical aid at a rate within their means. All the legitimate sick clubs could be drafted into the proposed Public Medical Service, which would soon be appreciated by the public, and prove a boon to the general practitioner. It would doubtless tend to the better, more willing, and more careful treatment of our poorer patients.

No lawyer's fee is less than 6*s.* 8*d.* A modified liberal code of charges would prove as beneficial, I think, to the medical as it is to the legal profession. But union is strength, and we must, if we wish to succeed, all pull together. The issue is almost a vital one, and worthy of the attention of the philanthropist as well as of all medical men who love their profession and desire *to live by it*, to work honestly in it, and to do their best alike for poor as well as rich.—Yours truly,

FRED. H. ALDERSON, M.D.

DYSIDROSIS POMPHOLYX: ITS TREATMENT AND ITS ANALOGY TO TRACHOMA.

To the Editor of The Provincial Medical Journal.

Sir,—I have recently had under my care two cases of the above skin disease. In one case the patient had suffered from a mild attack a year ago, and I then affected a cure with carbolic acid ointment, and iron internally. The second attack was more severe, and caused great inflammatory mischief, affecting the lymphatics. I applied a lotion of the biniodide of mercury in sodic iodide, 1 in 500, and cured the disease in a few days. In the second case eczema existed as a complication, which I cured with borozinc ointment, and the lotion. I think that this disease bears a very close resemblance to trachoma, because both present a "sago-grain" appearance and both are due to the growth of a micro-organism.—I am, Sir, yours truly,

C. R. ILLINGWORTH, M.D.

VOTING BY PROXY.

To the Editor of The Provincial Medical Journal.

Sir,—Although I think matters connected with the British Medical Association are usually better discussed in the columns of its own journal, I accept Dr. Woods' challenge because I am anxious to do what I can to prevent unnecessary waste of time in discussing the proposal which he has made, and which I believe, if carried, would cause a great deal of inconvenience, expense, and difficulty to the association. At the present time, every one who attends the Annual Meeting must admit, the attempt to discuss general questions concerning the well-being of the profession is a dismal failure, owing to the want of time for this purpose, and, we must also suppose, the lack of general interest. These motions are the dread of the officials of the association, who foresee only waste of time, disorder, and ill-feeling, as their result. It would be much better that gentlemen interested in a particular question should bring it before their own branch, and if they are able, pass a resolution instructing the branch representatives to bring it before the Council of the Association, and to urge action in the desired direction. The subject would then have a chance of candid and considerate discussion, and the association would not be rushed into any hasty and possibly imprudent course.

Dr. Woods' objection to this is that there are a number of unattached members. I agree to this, and will heartily support any reform of the constitution of the association which would remedy this defect. The inconvenience of his proposal would be that the association would be constantly the sport of agitators, who would insist on general polls on any question they cared to bring forward, an undertaking involving considerable trouble and expense. It would be necessary for the representatives of each branch to obtain proxies from as many members as possible, so as to support their own views at general meetings, or the elected representatives of the branches would be overwhelmed by the votes of the least responsible and least active members of the association. In short, Dr. Wood's proposal amounts to a revolution in the management of the association. It would withdraw matters from the calm consideration of the Council, and submit every burning question to the decision of a *plebiscitum*. No institution could be governed on such a basis; it is the democratic idea run mad. If the present Council is not elected on a sufficiently broad basis, alter it and improve it if you can; but, unless you wish to destroy the association, do not weaken the Council, and do not encourage the attempt to solve burning questions by votes at general meetings, either with or without the assistance of proxies.

Birmingham. ROBERT SAUNDBY, M.D., F.R.C.P.

[Dr. Woods suggests rather unfairly that those who oppose him are those who wish to make the association purely scientific, and who care nothing for the general interests of the profession. I think I can afford to ignore this innuendo; at least, those who meet me on the Council of the association and on its committees know better.]

Bibliographical Record.

BOOKS, PAMPHLETS, etc., RECEIVED.

Reports of the Medical Officer of Health for the city of Aberdeen.

On the Animal Alkaloids, the Ptomaines, Leucomaines, and Extractures in their Pathological Relations. Second edition. By Sir William Aitken, Kt., M.D., etc. London: H. K. Lewis.
